### **Abstract**

Information Systems can help the peoples by providing many varieties of information's to peoples. We can access the information's anywhere by using the World Wide Web. But the information's can't be viewed by the blind peoples. Due to their inability in accessing information from written text documents, blind people face tremendous difficulties in accessing information through web. In this paper, we propose an automatic summarization system to ease web browsing for visually impaired people on handheld devices. In particular, we propose a new architecture for summarizing Semantic Textual Units [2] based on efficient algorithms for linguistic treatment [3][6] which allow real time processing and deeper linguistic analysis of web pages, thus allowing quality content visualization. Moreover, we present a text-to-speech interface to ease the understanding of web pages content. To our knowledge, this is the first attempt to use both statistical and linguistic techniques for text summarization for browsing on mobile devices.

Keywords: Web Browsing, Semantic Textual Units, Linguistic Treatment, Text – to- Speech Interface.

### **1. INTRODUCTION**

Visually impaired people are info-excluded due to the overwhelming task they face to read information on the web. Unlike fully capacitated people, blind people cannot read information by just scanning it quickly i.e. they can not read texts transversally. As a consequence, they have to come through all sentences of web pages to understand if a document is interesting or not. To solve this problem, we propose an automatic summarization server-based architecture for web browsing on handheld devices. In particular, we introduce five different efficient methods for summarizing subparts of web pages in real-time. Two main approaches have already been proposed in the literature. First, some methodologies

such as [2][14] use simple but fast summarization techniques to produce results in real-time. However, they show low quality contents for visualization as they do not linguistically process the web pages.

Second, some works apply linguistic processing and rely on *ad hoc* heuristics [7] to produce compressed contents but can not be used in a real-time environment. Moreover, they do not use statistical evidence which is a key factor for high quality summarization. As a consequence, we propose a new architecture, called XSMobile, for summarizing Semantic Textual Units [2] based on efficient algorithms for linguistic treatment [3][6] that allow real-time processing and deeper linguistic analysis of web pages.

Web browsers for the visually handicapped people in the past have been limited to converting documents to Braille or speech, or extracting text and filtering. However, the human aspects of web surfing for blind people have not been adequately addressed. This paper presents an architecture of an open source, light weight web browser that makes it easy for the visually handicapped people to surf the web. The proposed architecture allows a blind person to navigate any web content through simple speech commands and voice feedback to any keyboard operation. The browser will have an integrated text extraction engine that inspects the content of the page to construct a structured representation. The internal nodes of the structure represent various levels of abstraction of the content. This helps in easy and flexible navigation of the page so as to rapidly home into objects of interest. Finally, the browser is integrated to an automatic Text-To-Speech and Text-To-Braille transliteration engine that outputs the selected text in the form of speech or Braille.

The present article presents the results of a project focused on a tool for visually impaired people. This project consists of two parts, one, a web-browser, and two, a web-page reader. Both tools are developed

to allow blind people to navigate the internet using Google and Microsoft SAPI together with Java based programs in Spanish.

Macias, M. Departament de Informatica, University. de Extremadura, Spain Sanchez,F.

Currently, the vast majority of content published on the Internet is inaccessible to visually impaired users. However, designers have guidelines that guarantee the accessibility of pages as well as software tools to facilitate this task. It is necessary to consider the user's perspective too, allowing him/her to participate in the restructuring or presentation process of content. There are few software tools which are able to do this. KAI (Accessibility Kit for the Internet) considers both the user and the designer. It classifies the different components of a published Web page and presents them to the user according to his/her needs. At the same time, it improves their accessibility. KAI is based on a new language, BML (Blind Markup Language) that helps authors develop better structured pages. It provides two levels of independence: original Web code and user platform.

There are several speech-based Internet browsers for visually challenged currently available in the market. These are proved to be helpful in information and knowledge gathering to the target group. But a dialogue based browser with all the functionalities like browsing, form-filling, mailing, image and graphics description etc. is still far distant from reality. An attempt has been made to resolve some of these issues in this paper. The prototype designed by us is an enhancement over the existing systems in terms of its enhanced functionalities, better performance; two way dialogues based mechanism, and controlled delivery of information from internet.

### **3. PROPOSED WORK**

#### **3.1 Text Unit Identification**

One main problem to tackle is to define what to consider as a relevant text in a web page. Indeed, web pages often do not contain a coherent narrative structure [1]. For that purpose, [15] propose a C5.0 classifier to differentiate narrative paragraphs from non narrative ones. However, 34 features need to be calculated for each paragraph which turns this solution impractical for real-time applications. In the context of automatic construction of corpora from the web, [5] propose to use a language model based on Hidden

Markov Models using the SRILM toolkit [12]. This technique is certainly the most reliable one as it is based on the essence of the language but still needs to be tested in terms of processing time. Finally, [2] propose Semantic Textual Unit (STU) identification. In summary, STUs are page fragments marked with HTML markups which specifically identify pieces of text following the W3 consortium specifications. However, not all web pages respect the specifications and as a consequence text material may be lost. In this case, unmarked strings are considered STUs if they contain at least two sentences

#### **3.2 Linguistic Processing**

On the one hand, single nouns and single verbs usually convey most of the information in written texts. On the other hand, compound nouns (e.g. *hot dog*) and phrasal verbs (e.g. *take off*) are also frequently used in everyday language, usually to precisely express ideas and concepts that cannot be compressed into a single word. As a consequence, identifying these lexical items is likely to contribute to the performance of the extractive summarization process.

Subsequently, each STU in the web page is first morpho-syntactically tagged with the efficient TnT tagger [3]. Then, multiword units are extracted from each STU based on an efficient implementation of the SENTA2 multiword unit extractor [6] which shows time complexity  $\Theta(N \log N)$  where  $N$  is the number of words to process. Then, multiword units which respect the following regular expression are selected for quality content visualization: [Noun Noun\* | Adjective Noun\* | Noun Preposition Noun | Verb Adverb]. This technique is usual in the field of Terminology [14]. A good example can be seen in Figure 1 where the multiword unit "Web Services" is detected, where existing solutions [2][7][14] would at most consider both words "Web" and "Services" separately. Finally, we remove all stop words present in the STU. This process allows faster processing of the summarizing techniques as the Zipf's Law shows that stop words represent 1% of all the words in texts but cover 50% of its surface.

#### **3.3 Summarization Techniques**

Once all STUs have been linguistically processed, the next step of the extractive summarization architecture is to extract the most important sentences of each STU. In order to make this selection, each sentence in a STU is assigned a significance weight. The sentences with higher significance become the summary candidate sentences. Then, the compression rate defines the number of sentences to be visualized.

**3.3.1 Simple *tf.idf*:** This methodology is mainly used in Information Retrieval [13]. The sentence significance weight is the sum of the weights of its constituents divided by the length of the sentence. A well-known measure for assigning weights to words is the *tf.idf* score [11]. The *tf.idf* score is defined in Equation 1 where *w* is a word, *stu* a STU, *tf(w, stu)* the number of occurrences of *w* in *stu*, *|stu|* the number of words in the *stu* and *df(w)* the number of documents where *w* occurs.

$$tf\ idf(w,stu) = \frac{tf(w,stu)}{|stu|} * \frac{\log_2 N}{df(w)} \quad (1)$$

In our case, a dictionary of *idf* values is processed for each website where XSMobile is installed based on the collection of texts present in it. The process is web-based. All texts in the collection of the website are first linguistically processed as explained in Section 3. Then, the *n* most frequent words of the collection are extracted to produce query samples sent to the web search engine Google™. For each query, the first 10 most relevant urls are gathered given rise to 10\*n urls. Then, a web spider processes each url as deeply as possible in the hypertext structure and extracts all texts related to the initial query. Finally, after automatically gathering huge quantities of texts to approximate as best as possible the ideal *idf* values of the words, a XML dictionary of <word, *idf*> entries is produced. So, the sentence significance weight, *weight1(S, stu)*, is defined straightforwardly in Equation 2 where *|S|* stands for the number of words in *S* and *w<sub>i</sub>* is a word in *S*.

$$Weigh1(S,stu) = \frac{\sum_{i=1}^{|S|} tfidf(w_i,stu)}{|S|} \quad (2)$$

**3.3.2 Enhanced *tf.idf*:** In the field of Relevant Feedback, [13] propose a new score for sentence weighting that proves to perform better than the simple *tf.idf*. In particular, they propose a new weighting formula for word relevance, *W(.,.)*. It is defined in Equation 3 where *argmax<sub>w</sub>(tf(w,stu))* corresponds to the word with the highest frequency in the STU.

$$W(w,stu) = \frac{[0.5 + [0.5x\ tf(w,stu)]] * \log_2 N}{Argmax(tf(w,stu))\ df(w)} \quad (3)$$

Based on this weighting factor, [13] define a new sentence significance factor *weight2(S,stu)* which

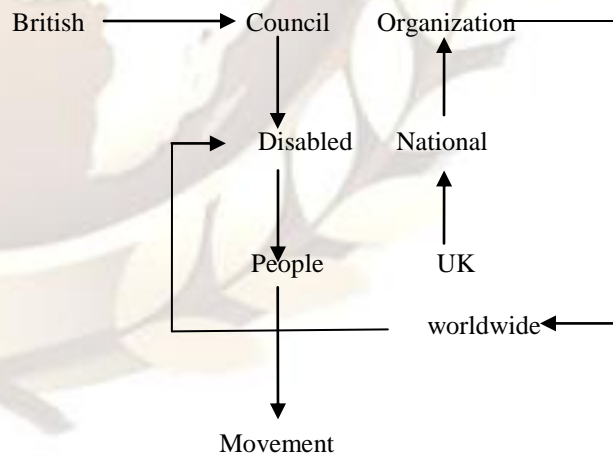

takes into account the normalization of the sentence length. The subjacent idea is to give more weight to sentences which are more content-bearing and central to the topic of the STU as shown in Equation 4 where *argmax(|S|)* is the length of the longest sentence in the STU

$$weigh2(S,stu) = \frac{|s|}{\sum_{i=0}^{|s|} W(w_i,stu) * |s|} \quad (4)$$

**3.3.3 The *rw.idf*:** Recently, [10] have proposed the TextRank algorithm. The basic idea of the algorithm is the same as the PageRank algorithm proposed by [4] i.e. the higher the number of votes that are cast for a vertex, the higher the importance of a vertex. Moreover, the importance of the vertex casting the vote determines how important the vote itself is. The score of a vertex *V<sub>i</sub>* is defined as in Equation 5 where *In(V<sub>i</sub>)* is the set of vertices that point to it, *Out(V<sub>j</sub>)* is the set of vertices that the vertex *V<sub>j</sub>* points to and *d* is a dumping factor.

$$S(V_i) = (1-d) + d * \sum_{J=fn(v_i)} \frac{1}{|Out(V_j)|} S(V_j) \quad (5)$$

In our case, each STU is represented as an un-weighted oriented graph being each word connected to its successor following sequential order in the text as in Figure 2.

After the graph is constructed, the score associated with each vertex is set to an initial value of 1, and the ranking algorithm is run on the graph for several iterations until it converges. So, each word is then weighted as in Equation 6

$$rw.idf(w,stu)=S(w)Xlog_2 \frac{N}{df(w)} \quad (6)$$

and the sentence significance weight,  $weight_3(S, stu)$ , is defined straightforwardly in Equation 7 where  $|S|$  stands for the number of words in  $S$  and  $w_i$  is a word in  $S$ .

$$weight_3(S,stu)= \frac{\sum_{i=1}^{|S|} rw.idf(w_{i,stu})}{|S|}$$

**3.3.4 Cluster Methodologies:** Luhn suggested in [9] that sentences in which the greatest number of frequently occurring distinct words are found in greatest physical proximity to each other, are likely to be important in describing the content of the document in which they occur<sup>4</sup>. The procedure proposed by [2], when applied to sentence  $S$ , works as follows. First, they mark all the significant words in  $S$ . A word is significant if its  $tf.idf$  is higher than a certain threshold  $T$ . Second, they find all clusters in  $S$  such that a cluster is a sequence of consecutive words in the sentence for which the following is true: (i) the sequence starts and ends with a significant word and (ii) fewer than  $D$  insignificant words must separate any two neighboring significant words within the sequence. Then, a weight is assigned to each cluster. This weight is the sum of the weights of all significant words within a cluster divided by the total number of words within the cluster. Finally, as a sentence may have multiple clusters, the maximum weighted cluster is taken as the sentence weight.

**3.4. Text-to-Speech Interface**

The Text-to-Speech module is a crucial issue for accessibility of Visually Impaired People to web page contents. For this purpose, we have integrated the Microsoft Speech Server into our architecture using the SALT markup language following the architecture proposed in Figure 3.

However, in future work, we will integrate a Speech-to-Speech module on the proper device in order to avoid the overload of the Microsoft Speech Server which has shown limitations for high amounts of requests.

**4. IMPLEMENTATION RESULT**

In this proposed paper, the web browser for visually impaired people is being implemented by using speech reorganization .when the blind people wants to search the web page content by moving the cursor in various location of the web browser. so that the blind people can hear through the speech. They can easily collect the information through this web browser as shown in figure.

## 5. CONCLUSION

In this paper, we proposed an automatic summarization system to help web browsing for visually impaired people on handheld devices. Unlike previous works [2][7][14], it is based on efficient algorithms [3][6] for linguistic treatment that allow real-time processing and deeper linguistic analysis for quality content visualization. The first results are very encouraging in terms of (1) quality of the content of the summaries, especially with the rw.idf, (2) processing time although the architecture is not still distributed over different processing units and (3) user interaction satisfaction. However, improvements must be taken into account. In particular, current work involves the integration of a Speech-to-Speech control interface which may provide a solution capable to compete with Braille PDAs that are expensive and difficult to use.
