Abstract
This paper presents a new approach for the reduction of high order discrete time Interval systems based on least squares method and Time moments matching technique. The proposed method is computationally simple and overcomes some of the limitations and drawbacks of the existing methods. A numerical example illustrates the proposed algorithm.

Keywords: Discrete time Interval systems, Least squares, Moment matching, Order Reduction.

1. Introduction
In general, the practical systems have uncertainties about its parameters. Thus practical systems will have coefficients that may vary and it is represented by in Very few methods are available in the literature for the model reduction of high order discrete time Interval systems.

The present work deals with the extending of the concept of least squares method about a general point ‘a’ to discrete time Interval systems combined with bilinear and inverse bilinear transformations.

2. Proposed Reduction Procedure
Let the n order discrete time Interval system be defined as

\[
H(z) = \left[\frac{[u_0^c, u_0^l] + [u_1^c, u_1^l]}{[v_0^c, v_0^l]} + \frac{[u_2^c, u_2^l]}{[v_1^c, v_1^l]} + \ldots + \frac{[u_{n-1}^c, u_{n-1}^l]}{[v_{n-2}^c, v_{n-2}^l]} + \frac{z^{n-2}}{[v_{n-1}^c, v_{n-1}^l]} + \frac{z^{n-1}}{[v_n^c, v_n^l]} \right]
\]

where, [u_i^c, u_i^l] for i = 0 to n-1 and [v_i^c, v_i^l] for i = 0 to n are the interval parameters.

Let the corresponding r order reduced model be synthesized as

\[
R_p(w) = \frac{\Delta P_0 + \Delta P_1 w + \Delta P_2 w^2 + \ldots + \Delta P_n w^{n-1}}{\Delta B_0 + \Delta B_1 w + \Delta B_2 w^2 + \ldots + \Delta B_n w^{n-1}}
\]

where \(a \) for i = 0 to n-1 and \(b_i \) for i = 0 to n are the uncertain coefficients of numerator and denominator respectively.

The n order original interval system in w-plane, \(H(w)\) is transformed to four fixed n order transfer functions using Kharitonov’s theorem defined as

\[
G_p(w) = \frac{\Delta P_0 + \Delta P_1 w + \Delta P_2 w^2 + \ldots + \Delta P_n w^{n-1}}{\Delta B_0 + \Delta B_1 w + \Delta B_2 w^2 + \ldots + \Delta B_n w^{n-1}}
\]

where \(p=1, 2, 3, 4\) and n = order of the original system.

Applying the Bilinear transformation \(z = \frac{1+w}{1-w}\) to the eqn. (1), the n order original discrete time Interval system is transformed to w-plane is represented as:

\[
H(w) = \left[\frac{[a_0^c, a_0^l] + [a_1^c, a_1^l]}{[b_0^c, b_0^l]} + \frac{[a_2^c, a_2^l]}{[b_1^c, b_1^l]} + \ldots + \frac{[a_{n-1}^c, a_{n-1}^l]}{[b_{n-2}^c, b_{n-2}^l]} + \frac{z^{n-2}}{[b_{n-1}^c, b_{n-1}^l]} + \frac{z^{n-1}}{[b_n^c, b_n^l]} \right]
\]

where \([a_i^c, a_i^l]\) for i = 0 to n-1 and \([b_i^c, b_i^l]\) for i = 0 to n are the uncertain coefficients of numerator and denominator respectively.

Let the corresponding r order reduced model be synthesized as

\[
R_p(w) = \frac{\Delta P_0 + \Delta P_1 w + \Delta P_2 w^2 + \ldots + \Delta P_n w^{n-1}}{\Delta B_0 + \Delta B_1 w + \Delta B_2 w^2 + \ldots + \Delta B_n w^{n-1}}
\]

Step1: Determination of the time moments and Markov parameters from the shifted original system: the time moments \(c_i\) can be obtained by expanding \(G_p(w+a)\) about \(w = 0\), as

\[
G_p(w + a) = \sum_{i=0}^{\infty} c_i w^i
\]

Similarly, if \(G_p(w + a)\) is expanded about \(w = \infty\), then the Markov parameters \(m_j\) are obtained by:

\[
G_p(w + a) = \sum_{i=1}^{\infty} m_j w^{-i}
\]

Equating the equation (5) and (6) to retain the time moments of the original system which generates the following set of equations:

\[
\begin{align*}
\sum_{i=0}^{\infty} c_i \frac{1}{i!} & = m_j \\
\sum_{i=1}^{\infty} c_i \frac{1}{i!} w + m_j \frac{1}{i!} & = 0
\end{align*}
\]

2096 | P a g e
or, \( H \ e = c \), in matrix vector form where the coefficients of ‘\( e_p \rangle \), the parameters of the reduced denominator obtained by least squares sense using the generalized inverse method;

\[
    e = (H^T H)^{-1} H^T c \quad \ldots (8)
\]

If the coefficients \( e_i \) given by the equation (8) do not constitute a stable denominator, then another row is to be added to the existing equation set so that the model assumes a matching of the next time moment of the original system:

\[
    \begin{bmatrix}
    c_{t+2} & c_{t+1} & \ldots & c_1 & c_0 \\
    c_{t+3} & c_{t+2} & \ldots & c_1 & c_0 \\
    \vdots & \vdots & \ddots & \vdots & \vdots \\
    c_{r+2} & c_{r+1} & \ldots & c_1 & c_0 \\
    c_{r+3} & c_{r+2} & \ldots & c_1 & c_0 \\
    \end{bmatrix}
\]

If the denominator polynomial is still not stable, then the \( H \) matrix and \( c \) vector are again to be extended by matching next time moments.

**Step 2:** The above step can also be generalized by including Markov parameters in the least square fitting process, as follows:

\[
    \begin{align*}
    d_{p0} &= e_{p0} c_0 \\
    d_{p1} &= e_{p1} c_0 + e_{p0} c_1 \\
    d_{p2} &= e_{p2} c_0 + e_{p1} c_1 + e_{p0} c_2 \\
    & \vdots \\
    d_{pr-1} &= e_{pr-1} c_0 + \cdots + e_{p0} c_{r-1} \\
    0 &= e_{pr-1} c_1 + \cdots + e_{p0} c_r \\
    0 &= e_{pr-1} c_2 + \cdots + e_{p0} c_{r+1} \\
    & \vdots \\
    0 &= e_{pr-1} c_t + \cdots + e_{p0} c_{r+t-1}
    \end{align*}
\]

and

\[
    \begin{align*}
    d_{pr-1} &= m_1 \\
    d_{pr-2} &= m_2 \ e_{pr-1} + m_2 \\
    d_{pt} &= m_3 \ e_{pt-1} + m_2 \ e_{pt-2} + \cdots + m_{r-t}
    \end{align*}
\]

where the \( c_i \) and \( m_i \) are the time moments proportional and Markov parameters of the system respectively. Elimination of \( d_i \) (\( i = t, t+1, \ldots, r-1 \)) in equation (11) by substituting into (10) gives the reduced denominator coefficients as the solution of:

\[
    X = \begin{bmatrix}
    0 \\
    m_2 \\
    m_3 \\
    \vdots \\
    m_{r-2} \\
    m_{r-1} \\
    \end{bmatrix}
\]

or \( H \ e = m \), in matrix vector form and \( e \) can be calculated \( e = (H^T H)^{-1} H^T m \) \ldots (13) are the coefficients of the reduced model denominator. If this estimate still does not yield a stable reduced denominator, then \( H \) and \( m \) in (12) are extended by another row, which corresponds to using the next Markov parameter from the full system in Least Squares match.

**Step 3:** Determination of the coefficients of the numerator of the reduced model \( R_p(w) \).

Once the coefficients of vector ‘\( e \)’ obtained from equation (13) apply inverse shift of \( w \rightarrow (w-a) \) and finally the \( r \)th order reduced denominator obtained as:

\[
    D_p(w) = E_{p0} + E_{p1} w + E_{p2} w^2 + \cdots + E_{pr} w^r
\]

**Step 4:** Determination of the coefficients of the numerator \( N_p(w) \) of the reduced model by moment matching.

Later calculate the reduced numerator as before by matching proper number of Time moments of \( G_p(w) \) to that of reduced model.

**Step 5:** Apply inverse bilinear transformation \( w = \frac{z-1}{z+1} \) to \( R(w) \) and determine \( R(z) \).

### 3. ILLUSTRATIVE EXAMPLE

Consider the 3rd order discrete interval system given by its transfer function:

\[
    G(z) = \frac{[3.25, 3.35] z^{4} + [3.5, 3.65] z^{3} + [2, 8.3]}{[5.4, 5.5] z^{4} + [1.1, 1.1] z^{3} + [1.5, 1.6] z + [2.1, 2.15]}
\]

On Applying Bilinear transformation, the above transfer function is obtained as:
Applying Kharitonov’s theorem, the four fixed coefficient transfer functions are:

\[ G_1(w) = \frac{2.85w^2 + 0.5w + 9.55}{4w^3 + 20.45w^2 + 9.15w + 10} \]
\[ G_2(w) = \frac{2.35w^2 + 1.1w + 9.55}{3.65w^3 + 20.45w^2 + 9.8w + 10} \]
\[ G_3(w) = \frac{2.4w^2 + 1.1w + 10}{3.65w^3 + 19.8w^2 + 9.8w + 10} \]
\[ G_4(w) = \frac{2.4w^2 + 1.1w + 10}{3.65w^3 + 19.8w^2 + 9.8w + 10} \]

Applying the proposed reduction procedure, the corresponding 2\textsuperscript{nd} order reduced models retaining 6 Time moments with Min. ISE are obtained as:

\[ R_1(w) = \frac{0.1126w^2 + 0.460399}{w^2 + 1.01301w + 0.65786} \quad \text{ISE} = 0.000844, \quad \text{HOM} = 0.273055 \]
\[ R_2(w) = \frac{0.18534w^2 + 0.440289}{w^2 + 1.03568w + 0.65207} \quad \text{ISE} = 0.002840, \quad \text{HOM} = 0.305723 \]
\[ R_3(w) = \frac{0.085543w^2 + 0.507396}{w^2 + 1.02172w + 0.65078} \quad \text{ISE} = 0.00310, \quad \text{HOM} = 0.273445 \]
\[ R_4(w) = \frac{0.15255w^2 + 0.451192}{w^2 + 1.11920w + 0.730050} \quad \text{ISE} = 0.002192, \quad \text{HOM} = 0.308396 \]

Thus the reduced interval model in \( w \)-plane is

\[ R(w) = \frac{[0.085543, 0.18534]w^2 + [0.440289, 0.507396]}{[1, 1.12]w^2 + [1, 1.017301, 1.11920]w + [0.65078, 0.730050]} \]

Applying inverse bilinear transformation

\[ R(z) = \frac{[0.525812, 0.69361]}{[2.608379, 2.84934]z^2 + [1, 1.017301, 1, 1.11920]z + [0.651078, 0.730050]} \]

To achieve the steady state matching of the responses of the original and reduced order models, the coefficients are multiplied with the gain correction factor,

\[ K = \frac{G(z)}{R(z)} \quad \mid_{z = 1} = 1 \]

Then the 2\textsuperscript{nd} order reduced model in \( z \)-domain is

\[ R(z) = \frac{[1.60936944, 1.81425935]z^2 + [0.701349806, 1.105128127]}{[2.608379, 2.84934]z^2 + [1, 1.017301, 1.557201]z + [1.651078, 1.730050]} \]

Using the Multi point Pade Approximation Method of O.Ismail [ the 2\textsuperscript{nd} order reduced model is obtained as:

\[ R(z) = \frac{[0.4717, 0.5998]z + [0.9965, 1.0075]}{[1, 1.4148, 1.4580]z^2 + [0.8054, 0.8374]z + [1, 1]} \]

The step responses of the proposed reduced model and that of O.Ismail are compared with the original interval system for lower bound and upper bound in Fig. 1 and Fig. 2 respectively.
Conclusion
A novel method is suggested for the order reduction of high order discrete interval systems based on Least – Squares method.
