ABSTRACT:
This paper proposes a software implementation for two level & three level inverter using space vector modulation techniques. This software implementation is performed by using MATLAB/SIMULINK software. This paper gives comparison between SVPWM Three phase two level & three level inverter. Two level inverter is the basic technique to implement any level. The main advantage of the two level inverter is simple in computation and also switching device selection is simple. It becomes difficult in high voltage & high power applications due to the increased switching losses and limited rating of the dc link voltage. Multilevel inverters are used in high voltage and high power applications with less harmonic contents. The harmonic contents of a three level inverter are less than that of two level inverters. And also rating of the dc link voltage is high. The simulation study reveals that three level inverter generates less THD compared to two-level inverter.

Key words—SVPWM, THD, TWO LEVEL & THREE LEVEL INVERTERS

I. INTRODUCTION
Three phase voltage-fed PWM inverters are recently growing popularity for multi-Megawatt industrial drive applications. The main reasons for this popularity are easy Sharing of large voltage between the series devices and the improvement of the harmonic quality at the output as compared to a two level inverter. The Space Vector PWM of a three level inverter provides the additional advantage of superior harmonic quality. Increasing the number of voltage levels in the inverter without requiring higher ratings on individual devices can increase the power rating. As the number of voltage levels increases, the harmonic content of the output voltage waveform decreases significantly. It is well known that multi-level inverters are suitable in high voltage and high power applications due to their ability to synthesize waveforms with better harmonic spectrum and attains higher voltages with limited maximum device ratings. As the number of levels is increased, the amount of switching devices and other component are also increased, making the inverter becoming more complex and costly [6].

In case of the conventional two level inverter configurations, the harmonic contains reduction of an inverter output is achieved mainly by raising the switching frequency. However in the field of high voltage, high power applications, and the switching frequency of the power device has to be restricted below 1 KHz due to the increased switching losses. So the harmonic reduction by raised switching frequency of a two-level inverter becomes more difficult in high power applications. In addition, as the D.C. link voltage of a two-level inverter is limited by voltage rating of the switching device. From the aspect of harmonic reduction and high Dc-link voltage level, three-level approach looks like a most alternative.

II. ANALYSIS OF TWO LEVEL SVPWM INVERTER

Space Vector Modulation (SVM) [1] was originally developed as vector approach to Pulse Width Modulation for three phase inverters. It is a more sophisticated technique for generating sine wave that provides higher voltages with lower total harmonic distortion. The circuit model of a typical three-phase two level voltage source PWM inverter is shown in “Figure.1”. S1 to S6 are the six power switches that shape the output, which are controlled by the switching variable a, a’, b, b’, c and c’. When an upper transistor is switched on, i.e., when a, b or c is 1, the corresponding lower transistor is switched on, i.e., the corresponding a’, b’ or c’ is zero. Therefore, the on and off states of the transistors can be used to determine the output voltage. In this PWM technique180° conduction is used for generating the
gating signals. If two switches, one upper and one lower switch conduct at the same time such that the output voltage is \( \pm V_s \), the switch state is 1. If these two switches are off at the same time, the switch state is 0.

2.1 SWITCHING STATES

![Figure 2: Switching states of two level inverter][5]

The total number of switching states in an “N” level inverter is “\( N^2 \)”. So the total number of switching states in a “2” level inverter is “2” that is 8 switching states. They are \( S_0, S_1, S_2, S_3, S_4, S_5, S_6 \), and \( S_7 \). \( S_0 \) and \( S_7 \) are called as zero switching states because during which there is no power flow from source to load. \( S_1 \) to \( S_6 \) are called as active switching states.

2.2 SPACE VECTOR DIAGRAM OF TWO-LEVEL INVERTER

![Figure 3: Space vector diagram of two level inverter][5]

Space vector diagram is divided into six sectors. The duration of each sector is \( 60^\circ \). \( V_1, V_2, V_3, V_4, V_5, V_6 \) are active voltage vectors and \( V_0 \) & \( V_7 \) are zero voltage vectors. Zero vectors are placed at origin. The lengths of vectors \( V_1 \) to \( V_6 \) are unity and lengths of \( V_0 \) and \( V_7 \) are zero. The space vector \( V_i \) constituted by the pole voltage \( V_{ao}, V_{bo}, \) and \( V_{co} \) is defined as [4]

\[
V_i = V_{ao} + V_{bo} e^{j(2\pi/3)} + V_{co} e^{j(4\pi/3)}
\]

\[
V_{ao} = V_a + V_b + V_c \quad \text{and} \quad V_{co} = V_c + V_a + V_b
\]

\[
V_{ao} + V_{bo} + V_{co} = 0
\]

\[
V_{ao} = (V_{ao} + V_{bo} + V_{co}) / 3
\]

The relation between the line voltages and the pole voltages is given by

\[
V_{ao} = V_{ao} - V_{bo}, \quad V_{bc} = V_{bo} - V_{co}, \quad V_{ca} = V_{co} - V_{ao}
\]

For example voltage vector \( V_i \) that is 100

\[
V_{ao} = V_{dc}, \quad V_{bo} = 0 \quad \text{and} \quad V_{co} = 0, \text{then} \quad V_i = (V_{ao} + 0 + 0) / 3 = V_{ao} / 3
\]

\[
V_{ao} = V_{ao} - V_{bo} = (2/3) V_{dc}, \quad V_{bc} = V_{bo} - V_{co} = (-1/3) V_{dc}, \quad V_{ca} = V_{co} - V_{ao} = (-1/3) V_{dc}
\]

\[
V_{ab} = V_{ao} + V_{bo} = V_{dc}, \quad V_{bc} = V_{bo} - V_{co} = 0 \quad \text{and} \quad V_{ca} = V_{co} - V_{ao} = -V_{dc}
\]

III. ANALYSIS OF THREE LEVEL INVERTER

![Figure 4: Three Phase three level voltage source inverter][5]

The circuit [2] employs 12 power switching devices and 6 clamping diodes. Each arm contains four IGBTs, four anti parallel diodes and two neutral clamping diodes. And the dc bus voltage is split into three levels by two series connected bulk capacitors \( C_1 \), \( C_2 \) two capacitors have been used to divide the DC link voltage into three voltage levels, thus the name of 3-level. The middle point of the two capacitors can be defined as the neutral point 0.

The output voltage \( V_{ao} \) has three different states: \( V_{ao}/2 \), 0 and \( -V_{ao}/2 \). For voltage level +\( V_{ao}/2 \), switches \( S_1 \) & \( S_2 \) need to be turned on. For voltage level 0, switches \( S_2 \) & \( S_3 \) need to be turned on. For voltage level -\( V_{ao}/2 \) switches \( S_3 \) & \( S_4 \) need to be turned

on. We can define these states as 2, 1, and 0. Using switching variable $S_0$ and dc bus voltage $V_{dc}$, the output phase voltage $V_{ao}$ [2] is obtained as follows:

$$V_{ao} = (S_0^2) / 2 \times V_{dc}$$

### 3.1 SPACE VECTOR DIAGRAM OF THREE LEVEL SVM PWM INVERTER

The plane can be divided into 6 major triangular sectors (I to VI) by large voltage vectors and zero voltage vectors. Each major sector represents 60° of the fundamental cycle. Within each major sector, there are 4 minor triangular sectors. There are totally 24 minor sectors in the plane. Large voltage vectors are $V_{13}$, $V_{14}$, $V_{15}$, $V_{16}$, $V_{17}$, and $V_{18}$. Medium voltage vectors are $V_2$, $V_8$, $V_9$, $V_{10}$, $V_{11}$, and $V_{12}$. Small voltage vectors are $V_1$, $V_2$, $V_3$, $V_4$, $V_5$, and $V_6$.

Zero voltage vector is $V_0$. Each major sector can be identified by using space vector phase angle, $\alpha$ is calculated and then sector, in which the command vector $V^*$ is located, is determined as:

- If $\alpha$ is between 0 ≤ $\alpha$ < 60°, and $V^*$ will be in major sector I.
- If $\alpha$ is between 60 ≤ $\alpha$ < 120°, and $V^*$ will be in major sector II.
- If $\alpha$ is between 120 ≤ $\alpha$ < 180°, and $V^*$ will be in major sector III.
- If $\alpha$ is between 180 ≤ $\alpha$ < 240°, and $V^*$ will be in major sector IV.
- If $\alpha$ is between 240 ≤ $\alpha$ < 300°, and $V^*$ will be in major sector V.
- If $\alpha$ is between 300 ≤ $\alpha$ < 360°, and $V^*$ will be in major sector VI.

### 3.2 DETERMINATION OF REGION IN A PARTICULAR SECTOR

For example we are taking the space vector diagram of sector I for determining the particular region in a sector I. Sector I contains 4 minor triangular sectors, $D_1$, $D_2$, $D_3$, and $D_4$ are 4 minor triangular sectors. In each of the four minor regions, the reference vector $V_{ref}$ located in one of the 4 regions, where each region is limited by three adjacent vectors. Then

$$V_{ref} = V^* = V_x (T_x / T_s) + V_y (T_y / T_s) + V_z (T_z / T_s)$$

$$T_x / T_s + T_y / T_s + T_z / T_s = 1$$

Based on the principle of vector synthesis, the following equations can be written as:

$$X + Y + Z = 1$$

$$V_x + V_y + V_z = V^*$$

Modulation ratio $M = (V^* / 2/3 V_{dc}) = (3 V^* / 2 V_{dc})$

As shown in figure 5, the boundaries of modulation ratio are Mark1, Mark 2, and Mark3. The equation [2] forms of them are obtained as follows:

$$Mark 1 = \frac{\sqrt{3}/2}{\sqrt{3} \cos \theta + \sin \theta}$$

$$Mark 2 = \frac{\sqrt{3}/2}{\sqrt{3} \cos \theta - \sin \theta}, \theta \leq \pi/6$$

$$Mark 3 = \frac{\sqrt{3}}{\sqrt{3} \cos \theta + \sin \theta}, \theta > \pi/6$$

Figure 5: Space vector diagram of three level inverter

![Space vector diagram of three level inverter](image-url)
3.3 CALCULATION OF ACTIVE VECTOR SWITCHING TIME PERIOD

a) When the modulation ratio M < Mark1, then the rotating voltage vector V* will be in sector D1 (Region 1). In a three level inverter, switching time calculation is based on the location of reference vector with in a sector. In one sampling interval, the output voltage vector V* can be written

\[ V^* = V_0 (T_1/T_T) + V_1 (T_2/T_T) + V_2 (T_3/T_T) \]

As shown in figure.5 V* is synthesized by V_0, V_1, and V_2. In sector D1, the length of zero voltage vector V_0 is zero and length of large voltage vector is 1. Then V* T_1 = V_1 (T_1/T_T) + V_2 (T_2/T_T) + V_0 (T_3/T_T) V_1 X + V_2 Y + V_0 Z = V* V* = M (cos \theta + j sin \theta), V_1 = \frac{1}{2}, V_2 = \frac{1}{2} (cos \theta + j sin \theta) and V_0 = 0.

M (cos \theta + j sin \theta) = \frac{1}{2}  (cos 60^\circ + j sin 60^\circ) \]

\[ X + Y + Z = 1 \]

(2) Using (1) & (2), we can obtain X, Y and Z as follows

\[ \begin{aligned}
X &= 2m \left[ \cos \theta - \frac{\sin \theta}{\sqrt{3}} \right] \\
Y &= m \left[ 4\sin \theta \right] \\
Z &= 1 - 2m\left[ \cos \theta + \frac{\sin \theta}{\sqrt{3}} \right]
\end{aligned} \]

b) Similarly when the modulation ratio Mark1 < M < Mark2, then V* will be in sector D2 (Region 2). V* can be synthesized by V_1, V_2, and V_7.

\[ V^* = V_1 (T_1/T_T) + V_2 (T_2/T_T) + V_7 (T_3/T_T) \]

In sector D2, the length of zero voltage vector V_7 is zero, and length of large voltage vector is 1. V* T_1 = V_1 (T_1/T_T) + V_2 (T_2/T_T) + V_7 (T_3/T_T) V_1 X + V_2 Y + V_7 Z = V* \]

Using (3) & (2), we can obtain X, Y, and Z as follows

\[ \begin{aligned}
X &= 1 - m \left[ \frac{4\sin \theta}{\sqrt{3}} \right] \\
Y &= 1 - 2m \left[ \cos \theta - \frac{\sin \theta}{\sqrt{3}} \right] \\
Z &= -1 + 2m\left[ \cos \theta + \frac{\sin \theta}{\sqrt{3}} \right]
\end{aligned} \]

c) Similarly when the modulation ratio Mark2 < M < Mark3 and 0 < \theta < 30 deg, then V* will be in sector D13 (Region 3). V_1, V_13 and V_7 are selected to synthesize V*.

\[ V^* = V_1 (T_1/T_T) + V_{13} (T_2/T_T) + V_7 (T_3/T_T) \]

In sector D13, the length of zero voltage vector V_7 is zero, and length of large voltage vector is 1. V* T_1 = V_1 (T_1/T_T) + V_{13} (T_2/T_T) + V_7 (T_3/T_T) V_1 X + V_{13} Y + V_7 Z = V* \]

Using (4) & (2), we can obtain X, Y, and Z as follows

\[ \begin{aligned}
X &= -1 + 2m \left[ \cos \theta - \frac{\sin \theta}{\sqrt{3}} \right] \\
Y &= m \left[ 4\sin \theta \right] \\
Z &= 2 - 2m\left[ \cos \theta + \frac{\sin \theta}{\sqrt{3}} \right]
\end{aligned} \]

d) When the modulation ratio Mark2 < M < Mark3 and 0 < \theta < 30 deg, then V* will be in sector D13 (Region 3). V_2, V_7 and V_14 are selected to synthesize V*.

\[ V^* = V_2 (T_1/T_T) + V_7 (T_2/T_T) + V_{14} (T_3/T_T) \]

In sector D14, the length of zero voltage vector V_7 is zero, and length of large voltage vector is 1.

V* T_1 = V_2 (T_1/T_T) + V_{14} (T_2/T_T) + V_7 (T_3/T_T) V_2 X + V_{14} Y + V_7 Z = V* \]

Using (5) & (2), we can obtain X, Y, and Z as follows

\[ \begin{aligned}
X &= 2m \left[ \cos \theta - \frac{\sin \theta}{\sqrt{3}} \right] \\
Y &= -1 + m \left[ 4\sin \theta \right] \\
Z &= 2 - 2m\left[ \cos \theta + \frac{\sin \theta}{\sqrt{3}} \right]
\end{aligned} \]

The simulation results suggest that three-level SVPWM can achieve less harmonic distortion compared to two-level SVPWM. And also these
results shows that when the number of levels increasing, harmonics are reduced.

VII. CONCLUSION
In this paper, SVPWM technique is used to reduce the harmonics. SVPWM technique has an advantage of fast dynamic response, Easy digital implementation, Lower switching losses, Better harmonic performance. As the number of voltage levels increases, the harmonic content of the output voltage waveform decreases significantly. But the main difficulty in this SVPWM is it becomes very difficult when the levels increases and it is complex in some steps that is selection of switching states. A low harmonic content of a proposed 3-level NPC inverter simulation model has been successfully developed with RL load in this paper. The basic implementation is used for future works with high levels that is more than three level inverters. And also the present implementation is used for a new simplified space vector PWM method for three-level inverters.

| TABLE.V SIMULATION PARAMETERS FOR TWO LEVEL & THREE LEVEL SVPWM INVERTER |
|-----------------------------------------------|------------------|
| **Input DC link voltage (V_{dc}) for 2 level inverter** | 400V            |
