Abstract
Spices played a dramatic role in civilization and in the history of nations. The delightful flavour and pungency of spices make them indispensable in the preparation of palatable dishes. In addition, they are reputed to possess several medicinal and pharmacological properties and hence find position in the preparation of a number of medicines. Antioxidant compounds in food play important roles as health-protecting factors. Antioxidants are also widely used as additives in fats and oils and in food processing to prevent or delay spoilage of foods. Spices and some herbs have received increased attention as sources of many effective antioxidants. Since the middle ages, essential oils have been widely used for bactericidal, virucidal, fungicidal, antiparasitical, insecticidal, medicinal and cosmetic applications, especially nowadays in pharmaceutical, sanitary, cosmetic, agricultural and food industries. Because of the mode of extraction, mostly by distillation from aromatic plants, they contain a variety of volatile molecules such as terpenes and terpenoids, phenol-derived aromatic components and aliphatic components. In vitro physicochemical assays characterise most of them as antioxidants. This review presents some information about the most common and most-used spice antioxidants and its essential oils, biological effects and describes their isolation of antioxidant properties.

Keywords: Spices, Flavour, Antioxidants, Essential Oil, Volatile, Isolation and Pharmaceuticals.

I. Introduction
A spice is a dried seed, fruit, root, bark, or vegetable substance primarily used for flavoring, coloring or preserving food. Sometimes a spice is used to hide other flavors (Scully and Terence 1995). Spices are distinguished from herbs, which are parts of leafy green plants also used for flavoring or as garnish. According to Thomas et al., 2012, many spices have antimicrobial properties. This may explain why spices are more commonly used in warmer climates, which have more infectious disease, and why use of spices is especially prominent in meat, which is particularly susceptible to spoiling. A spice may have other uses, including medicinal, religious ritual, cosmetics or perfume production, or as a vegetable. For example, turmeric roots are consumed as a vegetable and garlic as an antibiotic.
An essential oil is a concentrated hydrophobic liquid containing volatile aroma compounds from plants. Essential oils are also known as volatile oils, ethereal oils, or aetherolea, or simply as the "oil of" the plant from which they were extracted, such as oil of clove. An oil is "essential" in the sense that it carries a distinctive scent, or essence, of the plant. Essential oils do not form a distinctive category for any medical, pharmacological, or culinary purpose.

Essential oils are generally extracted by distillation, often by using steam. Other processes include expression or solvent extraction. They are used in perfumes, cosmetics, soaps and other products, for flavoring food and drink, and for adding scents to incense and household cleaning products.

Essential oils have been used medicinally in history. Medical applications proposed by those who sell medicinal oils range from skin treatments to remedies for cancer and often are based solely on historical accounts of use of essential oils for these purposes. Claims for the efficacy of medical treatments, and treatment of cancers in particular, are now subject to regulation in most countries. As the use of essential oils has declined in evidence-based medicine; one must consult older textbooks for much information on their use (Sapeika and Norman 1963). Modern works are less inclined to generalize; rather than refer to "essential oils" as a class at all, they prefer to discuss specific compounds, such as methyl salicylate, rather than "oil of wintergreen".

Interest in essential oils Gilman et al., (1990) and Klaassen et al., (1991) has revived in recent decades with the popularity of aromatherapy, a branch of alternative medicine that claims that essential oils and other aromatic compounds have curative effects. Oils are volatilized or diluted in a carrier oil and used in massage, diffused in the air by a nebulizer, heated over a candle flame, or burned as incense.

II. Isolation of Antioxidants from spices

The number of contributions to isolation methods, techniques and activity testing of plant-origin antioxidants has significantly increased in recent years. Oxidation is one of the major causes of chemical spoilage, resulting in rancidity and/or deterioration of the nutritional quality, color, flavour, texture and safety of foods (Antolovichet al., 2002). There is at present increasing interest both in the industry and in scientific research for spices and aromatic herbs because of their strong antioxidant
and antimicrobial properties, which exceed many currently used natural and synthetic antioxidants. These properties are due to many substances, including some vitamins, flavonoids, terpenoids, carotenoids, phytoestrogens, minerals, etc. and render spices and some herbs or their antioxidant components as preservative agents in food (Calucci et al., 2003).

Except basic plant antioxidants some specific ones are characteristic for some important aromatic herbs and spices. Some examples of specific antioxidants are pimento from allspice; gallates, biflorin, its isomer euugenol and eugenyl acetate in clove (Anon, 1997; Lee and Shibamato, 2001; Peter, 2000); carnosol, carnosic acid, rosmanol, rosmaridiphenol, rosmadial and rosmariquinone, and various methyl and ethyl esters of these substances in rosemary (Bandoniene et al., 2002a, b; Pizzarelli et al., 2002); diarylheptanoids, gingerol and zingerone in ginger (Kikuzaki and Nakatani, 1993; Peter, 2000);
curcumin and tetradehydrocurcumin in turmeric (Relajakshmi and Narasimhan, 1996); flavonides, ferulicacid, piperine, phenolic amide feruperine in black pepper (Peter, 2000; Shahidi and Wanasundara, 1992; Nakatanier et al., 1986); derivatives of phenolic acids, flavonoids, tocopherols, rosmarinic acid and carvacrol in oregano (Peter, 2000; Pizzarelli et al., 2002); etc.

According to a phytochemical database (USDA, 2003), the number of different antioxidants in some plants can reach up to 40 (soybean 42, tea 36, fennel 35, onion 32, etc.). In this database, plants with the highest contents of antioxidants are walnut, betel nut, guava, coconut, and other less known plants. A list of some known substances with antioxidant activity in some very common spices is reported in Table 1. More information is available for examples on USDA food antioxidant database (USDA, 2003).

**Turmeric**  
(*Curcuma domestica*)  
Ascorbic-acid rhizome 0–293, beta-carotene rhizome, caffeic-acid rhizome 0–5, curcumin rhizome 9–38,888, eugenol essential oil 0–2100, p-coumaric-acid rhizome 0–345, protocatechuic-acid leaf, syringic-acid leaf, vanillicacid leaf

**III. Methods of antioxidant isolation from spices**

Spices can be added to foods in several forms: as whole spices, as ground spices, or as isolates from their extracts. Spices are aromatic and pungent food ingredients, therefore, their direct use as antioxidants is limited. The extraction procedure is determined by the types of antioxidant compounds to be extracted. Selection of a suitable extraction procedure can increase the antioxidant concentration relative to the plant material. For polyphenols and other antioxidants in plant materials three principal extraction techniques may be used: extraction using solvents, solid-phase extraction and supercritical extraction. It is advisable to complete the extraction using dry, frozen or lyophilized samples since some antioxidants are unstable or can be degraded by enzyme action in undried plant material. Several extraction techniques have been patented using solvents with different polarities, such as petrol ether, toluene, acetone, ethanol, methanol, ethyl acetate, and water. In addition, supercritical CO2-extraction and medium-chain triglycerides as carrier in a mechanical extraction process have been applied (Schwarz et al., 2001). Extraction using edible oil or fat is a very simple method. Natural material containing antioxidants, such as herbs and spices, is mixed with fats and/or oils, and the mixture is left at a room or moderately increased temperature for a defined time. The mixture is then filtered and used (Pokorny et al., 2001). For industrial purposes ethanol would probably be better than methanol as eventual solvent residues would be less toxic. A review of some extraction procedures used for preparation of some spice and herb antioxidant substances is given in Table 2.

The extracts obtained using organic solvents may be further concentrated, for instance, by molecular distillation. Essential oils present in spice extracts, are responsible for the characteristic aroma of the spices and can be removed by steam distillation at normal atmospheric pressure or in a vacuum, but antioxidant activity may be partially lost. Commercial antioxidant extracts from spices are available in powder form or as oily oleoresins (Pokorny et al., 2001).

V. Essential Oils

Essential oils are liquid products of steam or water distillation of plant parts (leaves, stems, bark, seeds, fruits, roots and plant exudates). Expression is used exclusively for the extraction of citrus oil from the fruit peel, because the chemical components of the oil are easily damaged by heat. Citrus oil production is now a major by-product process of the juice industry. An essential oil may contain up to
several hundred chemical compounds and this complex mixture of compounds gives the oil its characteristic fragrance and flavour. The plant parts can be extracted with organic solvents to produce oleoresins, concretes and absolutes or extracted with a near or supercritical solvent such as carbon dioxide to produce very high quality extracts. These oleoresins and extracts contain not only the volatile essential oil but also the concentrated non-volatile flavor components and these have wide application in the food and pharmaceutical industries. Essential oils have been largely employed for their properties already observed in nature, i.e. for their antibacterial, antifungal and insecticidal activities. At present, approximately 3000 essential oils are known, 300 of which are commercially important especially for the pharmaceutical, agronomic, food, sanitary, cosmetic and perfume industries.

Essential oils or some of their components are used in perfumes and make-up products, in sanitary products, in dentistry, in agriculture, as food preservers and additives, and as natural remedies. For example, d-limonene, geranyl acetate or d-carvone are employed in perfumes, creams, soaps, as flavor additives for food, as fragrances for household cleaning products and as industrial solvents.

Moreover, essential oils are used in massages as mixtures with vegetal oil or in baths but most frequently in aromatherapy. Some essential oils appear to exhibit particular medicinal properties that have been claimed to cure one or another organ dysfunction or systemic disorder (Silva et al., 2003; Hajhashemi et al., 2003; Perry et al., 2003).

Owing to the new attraction for natural products like essential oils, despite their wide use and being familiar to us as fragrances, it is important to develop a better understanding of their mode of biological action for new applications in human health, agriculture and the environment.

Some of them constitute effective alternatives or complements to synthetic compounds of the chemical industry, without showing the same secondary effects (Carson and Riley, 2003).

The most important spices traditionally traded throughout the world are products of tropical environments. The major exceptions to this group are the capsicums (chilli peppers, paprika), and coriander which are grown over a much wider range of tropical and non-tropical environments. Production of spices and essential oils in these wet and humid environments brings special difficulties for crop and product management. Drying the crop to ensure a stable stored product is of particular importance, and in wet humid environments this creates the need for efficient and effective drying systems.

VI. Biological effects of Essential Oils:

6.1 Cytotoxicity

As typical lipophiles, they pass through the cell wall and cytoplasmic membrane, disrupt the structure of their different layers of polysaccharides, fatty acids and phospholipids and permeabilize them. Cytotoxicity appears to include such membrane damage. Essential oils can coagulate the cytoplasm (Gustafson et al., 1998) and damage lipids and proteins (Ultee et al., 2002; Burt, 2004). Damage to the cell wall and membrane can lead to the leakage of macromolecules and to lysis (Juven et al., 1994; Gustafson et al., 1998; Cöket et al., 2000; Lamb et al., 2001; Oussalah et al., 2006). A Permeabilization of outer and inner mitochondrial membrane leads to cell death by apoptosis and necrosis (Yoon et al., 2000; Armstrong, 2006). It seems that chain reactions from the cell wall or the outer cell membrane invade the whole cell, through the membranes of different organelles like...
mitochondria and peroxisomes. Analyses of the lipid profiles by gas chromatography and of the cell envelope structure by scanning electron microscopy of several bacteria treated by some essential oil constituents showed a strong decrease in unsaturated and an increase in saturated fatty acids, as well as alterations of the cell envelopes (Di Pasqua et al., 2007). The induction of membrane damages has been also confirmed by a microarray analysis showing that Saccharomyces cerevisiae genes involved in ergosterol biosynthesis and sterol uptake, lipid metabolism, cell wall structure and function, detoxification and cellular transport are affected by a treatment with a-terpinene, a monocyclic monoterpen (Parveen et al., 2004). Until now, because of their mode of action affecting several targets at the same time, generally, no particular resistance or adaptation to essential oils has been described. However, a resistance to carvacrol of Bacillus cereus has been observed after growth in the presence of a sublethal carvacrol concentration. Pre-treatment with carvacrol diminished the fluidity of the membrane by changing its fatty acid ratio and composition (Ulteet al., 2000; DiPasqua et al., 2006). However, Rafii and Shahverdi (2007) have found a potentiation of the antibiotic nitrofurantoin at a sub-inhibitory concentration by essential oils against enterobacteria. Probably, given the effect of essential oils on cell membranes, the bacterial susceptibility or resistance depend on the mode of application and may suggest that the antibiotic has to be first in contact with the cells (Rafii and Shahverdi, 2007).

6.2 Phototoxicity

Some essential oils contain photoactive molecules like furocoumarins. Dijouget et al., (2006) have shown that Fusanusspicatuswood essential oil was not phototoxic but was very cytotoxic. In other words, cytotoxicity seems rather antagonistic to phototoxicity. In the case of photosynthesis, essential oils damage the cellular and organelle membranes and can act as prooxidants on proteins and DNA with production of reactive oxygen species (ROS), and light exposures do not add much to the overall reaction. In the case of phototoxicity, essential oils penetrate the cell without damaging the membranes or proteins and DNA. Obviously, cytotoxicity or photoxicity depends on the type of molecules present in the essential oils and their compartmentation in the cell, producing different types of radicals with or without light exposure. Thus, when studying an essential oil, it may be of interest to determine systematically it’s cytotoxic as well as its possible phototoxic capacity.

6.3 Nuclear mutagenicity

Several studies with various essential oils or their main components have demonstrated that, generally, most of them did not induce nuclear mutations, whatever the organism, i.e. bacteria, yeast or insect, with or without metabolic activation and whatever form of essential oils. For example, mentone of the peppermint essential oil gave positive results in the Ames test (Andersen and Jensen, 1984) Mentone was also found genotoxic in SMART test (Franziosset al., 1997). Anethol from fennel and anise essential oils was active in the Ames test (Nestman and Lee, 1983; Hasheminejad and Caldwell, 1994), however, the oxidized metabolic intermediates of these two molecules, trans-anethole oxide and Trans-asaroneoxide, were genotoxic in the Ames test and induced liver and skin cancers (Kim et al., 1999).

6.4 Cytoplasmic mutagenicity

Most of the mutagenicity (and anti-mutagenicity) studies on essential oils were performed on bacteria (Salmonellatyphimurium with Ames test, Escherichia coli with SOS Chromotest, and Bacillus subtilis with DNA Repair test). In this test system, it is impossible to distinguish the mode of action of essential oils and their targets. Usually, cytotoxicity, mutagenicity or anti-mutagenicity is assessed without being able to take into account possible defects in energy metabolism and respiration as direct or indirect causes. In this respect, tests in yeast (Saccharomyces cerevisiae) have been shown to be potentially very useful.

Taking advantage of the yeast system, it is possible to show that, among others, mitochondria are very important cellu lar targets for essential oils. Indeed, a relation between the deterioration of mitochondria and immediate changes of respiratory metabolism was demonstrated after treatment of yeast cells (Saccharomyces cerevisiae) with the tea tree essential oil (Schmolzet al., 1999). Cells of Saccharomyces cerevisiae showed a delay in ethanol production in the presence of cinnamon, clove, garlic, onion, oregano and thymessential oils, as estimated by the measure of the CO2 volume produced (Conner et al., 1984).

6.5 Carcinogenicity of the essential oils

Since most essential oils have been found to be cytotoxic without being mutagenic, it is likely that most of them are also devoid of carcinogenicity. However, some essential oils or rather some of their constituents may be considered as secondary carcinogens after metabolic activation (Guba, 2001). For example, essential oils like those from Salvia sclarea and Menthaarumaveniar provoke estrogen secretion which can induce estrogen-dependent cancers. Some others contain photosensitizing molecules like flavins, cyanin, porphyrins, hydrocarbures which can cause skin erythema or cancer. Pulegone, a component of essential oils from many mint species, can induce carcinogenesisthrough
metabolism generating the glutathione depletory pro-cresol (Zhou et al., 2004).

6.6 Antimutagenic properties of essential oils

Anti-mutagenic properties may be due to inhibition of penetration of the mutagens into the cells (Kada and Shimoi, 1987; Shangkleton et al., 1993), inactivation of the mutagens by direct scavenging, antioxidant capture of radicals produced by a mutagenor activation of cell antioxidant enzymes (Hartman and Shankel, 1990; Sharma et al., 2001; Ipek et al., 2005), or activation of enzymatic detoxification of mutagens for instance by plant extracts. Hernandez-Ceruelo seatet al. (2002) showed that Matricaria chamomilla essential oil inhibits SCEs induced by daunorubicine and methyl methane sulphonate mouse bone marrow cells. In a more recent study, they showed in the same system that Origanum compactum essential oil and some of its sub-fractions and constitutents are antimutagenic against the indirect-acting mutagen urethane and also against the direct-acting mutagenmethyl methanesulphonate (Mezzouget et al., 2007).

VII. Conclusion

In this view of the diversity of methods used for the isolation of antioxidants from spice and herb, their activity determination and biological effects of essential oils, there is a great need to standardize them for both these measurements. The search for more specific assays that give us chemical information, which could be related directly to oxidative deterioration of foods and biological systems, should be the objective of future research. Modern consumers ask for natural products, free of synthetic additives. Therefore, the application of natural antioxidants and essential oils will probably continue even the future, and it will be necessary to study their changes and interactions in more details. Scientists will look for new effective herbal sources with potent antioxidants and essential oils from natural herbal plants. All these plants extract their mixtures, isolates and concentrates with antioxidant and biological effects of essential oils have to meet all the requirements of human health safety.
