ABSTRACT
In most of the applications, the physical systems require a real-time operation to interface high speed constraints. In most of the applications, the physical systems require a real-time operation to interface high speed constraints. The Inter Integrated Circuits (I2C) is a 2-wired communication bus. Physically, it consists of 2 active wires: SDA (Serial Data), SCL (Serial Clock) and a ground connection. All I2C-bus compatible devices incorporate an on-chip interface which allows them to communicate directly with each other via the I2C-bus.

This paper focuses on the software implementation for I2C Driver and its interfacing with RAM. Specifically, this paper describes in detail an I2C Master connected to I2C Slave using an I2C bus. The I2C protocol was given by Philips Semiconductors for faster devices to communicate with slower devices and each other without data loss. The complete module is designed in VHDL and simulated in Xilinx ISE 14.5.

KEYWORDS: SCL, SDA, I2C Bus, RAM

I. INTRODUCTION:
The design of I2C bus controller is to interface between two devices for the purpose of communication. The presence an on chip RAM support for a data communication between the chip and a host computer to send data on the RAM. To minimize the system-level interconnect between integrated devices, I propose to transmit the contents of the RAM storing the results back to a host computer via a serial bus, the I2C Interface. The interconnect integrated circuit bus commonly known as the I2C bus which is a bi-directional, two-wire and serial communication standard protocol. The designed are simple but difficult for efficient integrated circuit (IC) control. The system is comprised of two bus lines, SCL (Serial Clock) and SDA (Serial Data). Standard I2C devices operate up to 100Kbps, while fast-mode devices operate at up to 400Kbps. Most of the I2C devices available today support 400Kbps operation.

II. LITERATURE SURVEY:
There are many reasons for using serial interface design much more important application includes serial communication like sensors communication with personal computer. Many common embedded system peripherals, such as analog-to-digital and digital-to-analog converters, LCDs, and temperature sensors, support serial interfaces. Serial interface allow processors to communicate without the need for shared memory and the problems they can create. There are Serial communication protocols like UART, CAN, USB, SPI, Inter IC. USB, SPI and UARTS are all just one type to point type protocol. USB uses multiplexer to communicate with other devices. Only I2C and CAN protocol uses software addressing. But only I2C is very simple to design and easy to maintain.

III. I2C BUS TERMINOLOGY:
- **Transmitter:** The device which sends the data or message to the receiver.
- **Receiver:** The device which receives the data or message from the bus.
- **Master:** The device which generates clock signals, initiates a transfer i.e. start condition and terminates a transfer i.e. stop condition. It may also act as a transmitter/receiver.
- **Slave:** The device addressed by a master. Also it may act as a transmitter/receiver.
- **Multi master:** More than one master can attempt control the bus at the same time without demeaning the data/message.
- **Arbitration:** It is a procedure to ensure that, if more than one master simultaneously tries to
control the bus, only one is allowed to do so and the data is not corrupted.

- **Synchronization:** It is a procedure to synchronize the clock signals of two or more devices.

**Figure 1. I²C bus configuration using masters and slaves**

### 3.1 Master and Slave:
A master is the device which initiates a data transfer on the bus and generates the clock signals to permit that transfer. At that time, any device addressed is considered a slave. Both lines are connected to a positive supply via a pull-up resistor, and remain HIGH when the bus is not busy. Each device is recognized by a unique address—whether it is a microcomputer, LCD driver, memory or keyboard interface—and can operate as either a transmitter or receiver, depending on the function of the device. A device generating a message or data is a transmitter, and a device receiving the message or data is a receiver. Obviously, a passive function like an LCD driver could only be a receiver, while a microcontroller or a memory can both transmit and receive data. When a data transfer takes place on the bus, a device can either be a master or a slave. The device which initiates the transfer, and generates the clock signals for this transfer, is the master. At that time any device addressed is considered a slave. It is important to note that a master could either be a transmitter or a receiver; a master microcontroller may send data to a RAM acting as a transmitter, and then interrogate the RAM for its contents acting as a receiver in both cases performing as the master initiating the transfer. In the same manner, a slave could be both a receiver and a transmitter. The I²C is a multi master bus. It is possible to have, in one system; a microcontroller may act as a master for one transfer, and then be the slave for another transfer, initiated by another processor on the network. The master/slave relationships on the bus are not permanent, and may change on each transfer.

### 3.2 Data Validity:
One data bit is transferred must remain stable during the HIGH period of the clock pulse in order to be valid. Changes in the data line at this time will be interpreted a eight bits long, is transferred serially with the most significant bit first, and is followed by an acknowledge bit. The clock pulse related to the acknowledge bit is generated by the master.

![Data validity condition](image)

**Figure 2 Data validity condition**

### 3.3 Byte format Data Transfer:
Every byte put on the SDA line must be 8 bits transmitted per transfer is unrestricted. Each byte has to be followed by an Acknowledge bit. Data is transferred with the Most Significant Bit (MSB) first. If a slave cannot receive or transmit another complete byte of data until it has performed other function, for example servicing an internal interrupt, it can hold the clock line SCL LOW to force the master into a wait state. Data transfer then continues when the slave is ready for another byte of data and releases clock line SCL.

![Data transfer on the I²C bus](image)

**Figure 3 Data transfer on the I²C bus [7]**

### IV. I²C Protocol:
Normally, a standard communication protocol consists of four parts:
1) START signal generation
2) Slave address transfer
3) Data transfer
4) STOP signal generation

#### 4.1 Transmitting a byte to a slave device:
After start condition has been sent, a byte can be transmitted to a slave by the master. This first byte after a start condition will identify the slave on the bus (address) and will select the mode of operation. The meaning of all following bytes depends on the slave.

![Data transfer](image)

**Figure 4 Data transfer**
4.2 Receiving a byte from a slave device:

Once the slave has been addressed and the slave has acknowledged this, a byte can be received from the slave if the R/W bit in the address was set to READ (set to ‘1’).

![Image showing transmission of a byte to a slave](image)

Figure 4 Transmission of a byte to a slave [8]

4.3 Design steps:

The functional description of I²C master has to be described in the VHDL language. That is called design module / core. The test bench program has to be developed to test the design module. The test bench gives the input to the design module & verifies the outputs. The test bench has to be written in such way to check the design module in all possible conditions.

V. SYSTEM ARCHITECTURE:

In this paper we are considering master as I²C controller and slave as SDRAM.

Figure 7 RTL schematic of designed I²C master controller
5.3 Advantages of I2C

1. Used for security sensitive applications like sensor connections, RFID, biometric devices, etc.
2. Common communication standards between microcontrollers and sensors.
3. Each device is recognised by its unique address and can operate as either a transmitter or receiver, depending upon the function of the device.
4. It provides enhanced security system.
5. Compatible with FPGA.

VI. SIMULATION RESULTS:

The VHDL code for I2C master controller is compiled in the Xilinx ISE 14.5 software tool. The test bench of this module is simulated and followings are the results.

Figure 9 Simulation result of write and read operation in I2C and RAM interface.

VII. CONCLUSION:

The simulation results showed that all the designed functional blocks of the system design are giving desired results and the system itself also giving the desired results. The interfacing done between the I2C master controller and RAM slave is successfully designed and is giving desired results. The design module is designed using VHDL. If the designer wants to design the module for any new technology than he only needs give the design to the logic synthesis tool as input and in result it will create the new gate level netlist and the tool itself optimize the timing and area for new technology.
