ABSTRACT
A multi-band microstrip patch antenna is developed and presented in this paper. The radiating elements in this antenna are composed of rectangular and triangular slots. These slots are engraved in the rectangular and triangular patch, joined together in one structure, and by single probe feed. The rectangular and triangular slots make the antenna to operate at multiband with relatively high gain. Therefore, this antenna can be used for wireless communication applications like WLAN, WiMax and radar system applications.

Key Words: Microstrip antennas, WiMax, WLAN.

I. INTRODUCTION
The design of an efficient wideband small size antenna for recent wireless applications is a major challenge. The microstrip patch antenna have found extensive applications in wireless communication systems owing to their advantages such as low profile, conformability, low fabrication cost and ease of integration with feed network. Microstrip patch antennas comes with drawback of narrow bandwidth, but wireless communication applications require broad bandwidth and relative high gain in order to achieve that we need to increase the substrate thickness, use of low dielectric substrates and various impedance matching feeding techniques and slotting techniques.

The concept of inserting slot array following a chebyshev distribution has proven to give remarkable functionality to an antenna [1]. It causes it to radiate significantly at different ranges of frequencies by using only one single feed point. But, it operates at less number of bands. A rectangle added to an equilateral triangle patch which is fed by a probe has a dual-band operation. With the rapid development of the wireless communication, the tri-band even multi-band antennas are needed to meet the requirement. Stacked microstrip antenna can achieve multi-band circular polarization (CP) radiation more easily than conventional antennas. Generally the stacked microstrip antennas can easily achieve dual-band operation [2]. But the limitations of the stacked microstrip antenna are the size, fabrication complexity, and cost.

In this paper, a single-feed multi-band microstrip patch antenna for wireless communication applications is presented. The multi-band is achieved by the patch, which represents a combination of a rectangular and an isosceles-triangular patch. The part of the patch formed by the isosceles triangle has the same area as the part formed by the rectangle. The rectangular slots are inserted into the rectangular part, and the triangular slots are inserted into the isosceles-triangular part of the patch. The whole system is fed by a coaxial probe into the substrate, with an input impedance of 50 Ω.

II. ANTENNA DESIGN
The basic structure of the proposed antenna, shown in Figure 1, consists of 3 layers. The lower layer constitutes of ground plane covered by the substrate having a width of 6 cm and a length of 15 cm. The middle layer is the substrate which has a dielectric constant ε_r = 2.2 and a height of 0.32 cm. The upper layer, which is the patch, consists of a rectangle with a length of 4 cm and a width of 3 cm, joined with an isosceles triangle having the same area as the rectangular patch and a base of 3 cm and a height of 8 cm.

Fig 1: Proposed Patch Structure

Inside the rectangular patch, two rectangular slots were inserted, one with a length of 3 cm and a width of 2 cm and the other with a length of 2.5 cm and a width of 1.5 cm. Also, inside the triangular patch, two triangular slots were inserted, one with a base of 2 cm and a height of 3 cm and the other with a base of 2.5 cm and a height of 2.25 cm. Stubs were used in order to join the rectangular and...
triangular slots with a length of 0.25 cm and a width of 0.2 cm. Placing of slots into the structure increases the beamwidth and increase resonances.

![Fig 2: Antenna model](image)

A parametric study and an optimization were done, in order to find the best feeding point of the structure. Several points were tested in order to get an overview of the defined functioning of the antenna, and to monitor the effect of both the rectangular and triangular slots. Figure 2 shows the proposed antenna on Rogers RT/ Duroid 5880 (tm). At first, the feeding point is chosen near the edge of the rectangle on its right-hand side. Results showed the operation of the antenna at less number of bands and also with low gain since the feeding point is bit far from the triangular slot where the multi-band operation is triggered. The feeding point is moved close to the radiating elements, in order to obtain optimum operation of the antenna. When the feeding point is closer to the triangular slot, the functioning of the antenna is more effective with relatively high gain.

**III. RESULTS**

**A. Return Losses**

![Fig 3: Return loss](image)

From Figure 3, the return losses of the proposed antenna at 2.67 GHz, 2.94 GHz, 3.59 GHz, 3.71 GHz and 4.75 GHz are -20.67 dB, -18.32 dB, -14.55 dB, -11.80 dB and -13.31 dB respectively.

**B. Gain**

![Fig 4: 2D- Gain Total](image)

![Fig 5: 3D- Gain Total](image)

Figure 4 and Figure 5 shows the gain of the antenna in 2D and 3D patterns. The gain of the proposed antenna is 6.9831 dB.

**C. Radiation Patterns**

The far electric fields of the rectangular patch are as follows
The radiation pattern for the proposed antenna for Phi and Theta at 0 deg and 90 deg is shown in the Figure 6 and Figure 7.

D. Field Distributions

The effect produced by an electric charge that exerts a force on charged objects is the E-field and its distribution in the patch is as shown in the Figure 8.

The measured intensity of a magnetic field in the patch is shown in Figure 9.

E. Current Distribution

Figure 10 shows the current distribution on the patch and from the figure it is clear that current distribution is more on the patch when compared to the substrate.

IV. CONCLUSION

From the analysis of multi-band rectangular-triangular slotted patch antenna on Rogers RT/Duroid 5880 (tm) substrate exhibits broadband resonance with relatively high gain. Thus, this model is well suitable for various S-band applications like wireless CCTV and wireless video links, WLAN applications (2.8 GHz), WLAN, WiMax, wireless WiMax, 802.1 6a applications (3.5 GHz) and also suitable for radar system applications (4.75 GHz). The antenna is successfully designed and optimized. The results show that the antenna not only has multi-band characteristic but also have good radiation patterns.
