**ABSTRACT**

Emergency Vehicles if delayed for a couple of seconds can cause a major loss for some. In this paper, a technique is proposed for movement of Emergency Vehicles that is Fire brigade and Ambulances in least time. The objective is to direct Fire brigades and Ambulances from source to Destination point in most efficient and effective time. Movement of these vehicles should be safe and vehicles should follow shortest path. The proposed method can help in selecting Emergency Vehicles from n-number of available Emergency Vehicles. Directing the shortest safest and least crowded path for the vehicles so that it can reach the accident point in least time. To make the movement of vehicles efficient, all traffic control signals should guide traffic to move in favour of clearing the emergency vehicle’s route. Check condition are made for assigning priority to emergency vehicles and higher priority emergency vehicles are facilitated first at a particular traffic control signal, if more than one vehicles waiting on a traffic square. The proposed technique avoids problems that usually arise with standard traffic control system. The Large number of vehicles on traffic square requires routing needs assignment of priority number, judgement and decision. Avoiding bottleneck at a traffic control signal, tracking based techniques will help for routing higher priority vehicles first.

**Keywords:** shortest path, Global Positioning System, Priority assignment, Emergency Vehicles, Dynamic Traffic Sequence Algorithm.

### I. INTRODUCTION

Public facilities as Emergency vehicles are Fire Brigade and Ambulance. At any time these vehicles are to be moved from source to destination point in most Effective time. Movement of these vehicles should be in-time and safe. This requires routing the emergency vehicle and making traffic control signal as per these vehicle movements as mentioned by Ahmad and Ehsan in [1]. The proposed tracking technique of using Global Positioning System avoids problems that usually arise with standard traffic control system. GPS (Global Positioning System) can use a ‘transmitter’ and receiver. The transmitters broadcast time codes and any receiver can receive the time codes from the transmitters and calculate exactly where vehicle is, that is, on the earth or in the sky above the earth. This GPS technique can be efficiently used with a multi emergency vehicle control and road junction area. It provides an efficient time management scheme, in which a dynamic time schedule is worked out in real time for the passage at traffic square. The real time operation of the system emulates and can help the judgment of a traffic policeman on duty. GPS provides identification information on a receiver that may both receive and transmit information. The GPS satellites continuously transmit digital radio signals that contain data on the satellites location and the exact time to the earth-bound receivers as mentioned by Elisabeth ILIE-ZUDOR[14]. The strength of the signal from the tag to the receiver may also be used as allocator used with multiple locaters to triangulate the position. This technology is best suited for smaller spaces, where the infrastructure is already in place to use it. GPS requires specialized scanners to read and transmit data.

### II. ASSIGNING CODES TO EMERGENCY VEHICLES AND TRAFFIC SIGNALS

Proposed system consists of six main units, which coordinates with each other and make sure that emergency Vehicles (Fire Brigade and Ambulance) reaches the accident place without any time lag. This system is divided into multiple units. Many important units altogether work for moving the vehicles from source to destination in least time using most feasible path. Where source is the current position of the Vehicle and destination is the accident point. The objective is to optimize the movements of ‘m’ number of vehicles in ‘n’ number of roads with in a fixed area as city or town with most optimized path and with least waiting time on a Traffic Control Signal (TCS). Traffic Junction Unit is a combination of GSM Modem, Microcontroller and Traffic Control unit. As per Table: 1 AB indicates ambulances’ and FB indicates fire brigades. Further AB[i] means ith number of ambulance FB[j] means jth number of fire brigade.
Similarly Table: 2 consist of district codes of two digits long. There are 27 districts in Chhattisgarh State. In each district let there are maximum 999 traffic control signals and it can range from 001 to 999. For example in Raipur districts as per Table: 2, first traffic control signal can be coded as 33001 and second traffic control signal as 33002 third will be 33003 and so on. Maximum Traffic control signals will be 33999. Taking another example say Durg district, Code for traffic control signal range from 22001 to 22999. First two digits indicate district code and next three digits indicate the traffic control signal number.

### III. ASSIGNING PRIORITY TO EMERGENCY VEHICLES:

Here we are checking the higher priority emergency vehicles on traffic control signal. On the basis of higher priority main server gives the direction to signals of a Traffic Junction Unit.

Q1. Fire Brigade Required? - Y/N
Q2. Ambulance Required? - Y/N
Q3. Major Fire Accident? - Y/N
Q4. Major Accident? - Y/N
Q5. Distance from main hospital?
Q6. Number of People Hurt?
Q7. Place of accident?

**Case 1** If AB1 has P1 priority and FB1 as P2 priority and both waiting at a traffic signal, than allow AB1 First with higher priority.

**Case 2** If major accident is yes than assign P1 to AB1 and one more accident case with answer as NO than P2 will be assigned to AB2 as lower priority. At common traffic signal First preference will be give to AB1.

**Case 3** If ambulance AB1 not available and number of people hurt as N where N>1 than search for FREE ambulance and allot P1 priority to it and others as priority P2, P3 etc.
Case 4 If number of people hurt in an accident is > than other one than higher priority will be assign to first case.

Case 5 If both accidents have minor causalities than we check the distance from ambulance point to accident point and if one is very far away say 10km and other is less. Higher priority is assigned to larger distance accident point.

Case 6 If both the accidents are minor. Distance is same than on the basis of number of causalities, priorities are assigned to emergency vehicles.

Case 7 If No emergency vehicle is free, than identification of nearest vehicle is must and Highest priority will be given to it.

Case 8 If Fire Brigade and Ambulance both are in traffic signal. If there is a major fire casualty then FB1 will get higher priority

Case 9 If Fire Brigade and Ambulance both are in traffic signal. If there is a major accident casualty then AB1 will get higher priority

Case 10. If Fire Brigade and Ambulance both are in traffic signal. If there is no a major fire casualties and accident case then FB1 will get higher priority

From cases 1 to 10 following algorithm will work.

Initialization

Array FB[5];----------List of Fire Brigade
Array AB[50];---------List of ambulance
Array TCS[999];---------List of Traffic Control Signal

Distance is D
True-Green
False-Red
Number of people hurt as P
Big=0
Number of causalities as C
Nearest vehicle NV

Main Algorithm for case 1
If Ambulance and Fire brigade Required is true
If TCS[k] is true
Than AB[j] = P1
Else
FB[i] = P2;

Main Algorithm for case 2
If Ambulance required and Major accident is true
If TCS[k] is true
Than AB[i] = P1;
Main Algorithm for case 3
If ambulance AB1 not avialable and major accident is true
If TCS[k] is true
Than AB[j]=P1;
If N>1 Major accident is true
Than AB2[i]=P2;

Main Algorithm for case 4
If Ambulance required, Major accident and Number of people hurt as P>1 is true
Than AB[i]=P1
If TCS [k] is true
Than AB[i]=P1
If big>1 Major accident and Number of people hurt as p>1 is true
Than AB[i]=P1

Main Algorithm for case 5
If Ambulance required, both accidents have minor causalities people hurt as P>1 is true
Than AB[i]=P1
If TCS [k] is true
Than AB[i]=P1
If D>10 Minor causalities and Number of people hurt as p>1 is true
Than AB[i]=P1

Main Algorithm for case 6
If Ambulance required, both accidents have minor and Number of causalities as D=C is true
Than AB[i]=P1
If TCS [k] is true
Than AB[i]=P1

Main Algorithm for case 7
If No emergency vehicle is free as AB and FB=0 is true
Than NV=P1
If TCS [k] is true
Than NV=P1

Main Algorithm for case 8
If there is a major Fire casualties is true
If TCS[k] is true
Else
FB[j] = P1
Main Algorithm for case 9
If there is a major and accident casualties is true
If TCS[k] is true
Else
AB[i] = P2;

Main Algorithm for case 10
If there is no a major fire casualties and accident case is true
If TCS[k] is true
Than FB[j] = P1
Else
AB[i] = P2;

NOTE: - Analyzing all cases one --- generate an algorithm to cover all type cases not only above mantianace ones.
By using above algorithm/or technology we can control the movement of emergency vehicles smoothing and efficiently within a city.

The flow chart given below represents the flow of the algorithm. In which after receiving the message from linked lights controller consider the factors like traffic density of the road, priority of the vehicles and queue length and starvation factor to decide the term of the light.

To display green signal. The flow chart given below not only works according to the number of vehicles near the traffic light but also solve the problem of starvation that can be arisen. Here the basic purpose of the algorithm is to calculate the green signal time duration and also provide the quality of the service to the Emergency vehicles like ambulance, Fire brigade and authoritative vehicles so that they can reach at their destination as early as possible and reduce the time wasted at the Red Light.

**IV. CONCLUSION**

This paper proposes a method for controlling the traffic signals in favor of Emergency vehicle movement at the time of emergency call. With this system the emergency vehicle can be reached to the accident spot without time lag. The proposed method proved to be effectual to control not only Fire Brigade, ambulances but also authoritative emergency vehicles. This Higher Priority of Emergency Vehicles System if implemented in state with large population like Chhattisgarh than it can also produce better results. We have implemented GPSF and GPSA to consider the priority of emergency vehicles. We apply Dynamic traffic sequence algorithm for the control of traffic sequence. Chhattisgarh include large number of tribal area and the propose system can be used in providing services to tribal people. Higher Priority of Emergency Vehicles System (HPEVS) is more accurate with no loss of time.
