ABSTRACT

The multiplier uses LUT's as memory for their computations. The antisymmetric product coding (APC) and odd-multiple-storage (OMS) techniques were proposed for look-up-table (LUT) design.

The APC and OMS techniques used for efficient memory-based multiplication. Therefore the combined approach provides a reduction in LUT size to one-fourth of the conventional LUT. APC approach is combined with the OMS technique, the two's complement operations could be very much simplified since the input address and LUT output could always be transformed into odd integers.

The proposed LUT design for small input sizes can be used for efficient implementation of high precision multiplication by input operand decomposition. The LUT based multiplier involves 5-bit word size. The area and delay can be improved. In multiplier if we reduce the number of LUT then delay can be reduced. Memory-based computing is well suited for many digital signal processing (DSP) algorithms, which involve multiplication with a fixed set of coefficients.

Keywords - Digital Signal Processing (DSP), Selective Sign Reversal (SSR), LUT..

I. INTRODUCTION

Along with the progressive device scaling, semiconductor memory has become cheaper, faster, and more power efficient. Moreover, according to the projections of the international technology road map for semiconductors, embedded memories will have dominating presence in the system-on—chips, which may exceed 90% of the total Soc content It has also been found that the transistor packing density of memory components is not only higher but also increasing much faster than those of logic components.

Apart from that, memory based computing structures are more regular than the multiply-accumulate structures and offer many other advantages, e.g., greater potential for high-throughput and low-latency implementation and less dynamic power consumption. Memory based computing is well suited for many digital signal processing (DSP) algorithms, which involve multiplication with a fixed set of coefficients.

A conventional lookup-table (LUT) based multiplier is shown in Fig. 1, where A is a fixed coefficient, and X is an input word to be multiplied with A. Assuming X to be a

positive binary number of word length L, there can be 2^L possible values of X, and accordingly, there can be 2^L possible values of product $C = A \cdot X$. Therefore, for memory-based, multiplication, an LUT of 2^L words, consisting of precomputed product values corresponding to all possible values of X, is conventionally used.

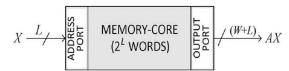

Fig.1.Conventional LUT-based multiplier

Several architectures have been reported in the literature for memory-based implementation of DSP algorithms involving orthogonal transforms and digital filters [2]-[8]. However, we do not find any significant work on LUT optimization for memory-based multiplication. I have presented a new approach to LUT design, where only the odd multiples of the fixed coefficient are required to be stored[9],, which we have referred to as the odd-multiple storage (OMS) scheme in this brief. In addition, we have shown that, by the antisymmetric product coding (APC) approach, the LUT size can also be reduced to half.

II. PROPOSED LUT OPTIMIZATIONS

We discuss here the proposed APC technique and its further optimization by combining it with a modified form of OMS.

A. APC for LUT Optimization

For simplicity of presentation, we assume both X and A to be positive integers. The product words for different values of X for L = 5 are shown in Table I. It may be observed in this Table I that the input word X on the first column of each row is the two's complement of that on the third column of the same row. the sum of product values corresponding to these two input values on the same row is 32A. Let the product values on the second and fourth columns of a row be u and v, respectively. Since one can write u = [(u + v)/2 - (v - u)/2] and v = [(u + v)/2 + (v - u)/2]u/2], for (u + v) = 32A, we can have u = 16A - [(v-u)/2]v = 16A + [(v-u)/2]. This behaviour of the product words can be used to reduce the LUT size, where, instead of storing u and v, only [(v - u)/2] is stored for a pair of input on a given row. The 4-bit LUT addresses and corresponding coded words are listed on the fifth and sixth columns of the table, respectively. Since the representation

Vol. 1, Issue 3, pp.699-703

of the product is derived from the antisymmetric behaviour of the products, we can name it as antisymmetric product code. The desired product could be obtained by Product word = $16A + (\text{sign value}) \times (\text{APCword})$ The product value for X = (10000) corresponds to APC value "zero," which could be derived by resetting the LUT output, instead of storing that in the LUT.

B. Modified OMS for LUT Optimization

For [9] the multiplication of any binary word X of size L, with a fixed coefficient A, instead of storing all the 2^L possible values of $C = A \cdot X$, only $(2^L/2)$ words corresponding to the odd multiples of A may be stored in the LUT, while all the even multiples of A could be derived by left-shift operations of one of those odd multiples. Based on the above assumptions, the LUT for the multiplication of an L-bit input with a W-bit coefficient could be designed by the following strategy

- A memory unit of [(2^L/2) + 1] words of (W +L)-bit width is used to store the product values, where the first (2^L/2) words are odd multiples of multiples of A, and the last word is zero.
- A barrel shifter for producing a maximum of (L 1) left shifts is used to derive all the even multiples of A
- The L-bit input word is mapped to the (L − 1)-bit address of the LUT by an address encoder, and control bits for the barrel shifter are derived by a control circuit.

The even multiples 2A, 4A, and 8A are derived by left-shift operations of A. Similarly, 6A and 12A are derived by left shifting 3A, while 10A and 14A are derived by left shifting 5A and 7A, respectively. A barrel shifter for producing a maximum of three left shifts could be used to derive all the even multiples of A.

III. IMPLEMENTATION OF LUT USING THE OPTIMIZATION SCHEME

Here, we discuss the implementation of the LUT-based Multiplier using the proposed scheme, where the LUT is Optimized by a combination of the proposed APC scheme and a modified OMS technique.

TABLE I APC Words for Different Input Values for L=5

Input, X	product values	Input, X	product values	address $x_3'x_2'x_1'x_0'$	APC words
00001	A	11111	31 <i>A</i>	1 1 1 1	15A
00010	2A	111110	30A	1 1 1 0	14A
00011	3A	11101	29A	1 1 0 1	13A
00100	4A	11100	28A	1 1 0 0	12A
00101	5A	11011	27A	1 0 1 1	11A
00110	6A	11010	26A	1 0 1 0	10A
00111	7A	11001	25A	1 0 0 1	9A
01000	8 <i>A</i>	11000	24A	1 0 0 0	8A
01001	9A	10111	23A	0 1 1 1	7A
01010	10A	10110	22A	0 1 1 0	6A
01011	11A	10101	21A	0 1 0 1	5A
01100	12A	10100	20A	0 1 0 0	4A
01101	13A	10011	19A	0 0 1 1	3A
01110	14A	10010	18A	0 0 1 0	2A
01111	15A	10001	17A	0 0 0 1	A
10000	16A	10000	16A	0 0 0 0	0

For $X = (0\ 0\ 0\ 0\ 0)$, the encoded word to be stored is 16A.

A. Implementation of the LUT Multiplier Using APC for $L=5\,$

The structure and function of the LUT based multiplier for L=5 using the APC technique is shown in Fig. 2. It consists of a four input LUT of 16 words to store the APC values of product words. Besides, it consists of an address mapping circuit and an add/subtract circuit. The address mapping circuit generates the desired address and can be optimized to be realized by three OR gates, and a NOT gate

V. Hari Krishna, N.C Pant / International Journal of Engineering Research and Applications (IJERA) ISSN: 2248-9622 www.ijera.com

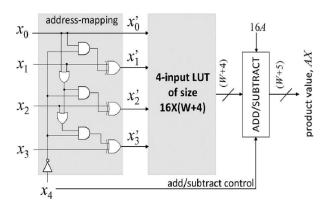

Fig. 2. LUT-based multiplier for L = 5 using the APC technique

B. Implementation of the Optimized LUT Using Modified OMS

The proposed APC–OMS combined design of the LUT for L = 5 and for any coefficient width W is shown in Fig. 3. It consists of an LUT of nine words of (W + 4)-bit width, a four-to-nine-line address decoder, a barrel shifter, an address generation circuit, and a control circuit for generating the RESET signal and control word (s1s0) for the barrel shifter. The precomputed values of A × (2i + 1) are stored as Pi, for i = 0, 1, 2, . . . , 7, at the eight consecutive locations of the memory array as specified in Table II. The decoder takes the 4-bit address from the address generator and generates nine word-select signals, i.e., {wi, for $0 \le i \le 8$ }, to select the referenced word from the LUT.

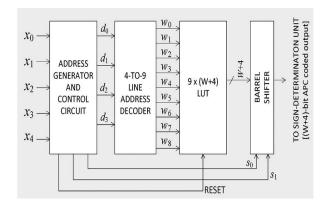

Fig.3.Proposed APC-OMS combined LUT design.

The 4-to-9-line decoder is a simple modification of 3-to-8-line decoder as shown in Fig.4(a). The control bits s0 and s1 to be used by the barrel shifter to produce the desired number of shifts of the LUT output are generated by the control circuit, according to the corresponding relations. The RESET signal can alternatively be generated as (d3 AND x4). The control circuit to generate the control word and RESET is shown in Fig. 4(b). The address-generator circuit receives the 5-bit input operand X and maps that onto the 4 bit address word (d3d2d1d0).

V. CONCLUSION

The proposed LUT multipliers for word size L = W = 5 and 6 bits are coded in VHDL and synthesized in XilinxISE 12.2i. Simulation Part is done in Modelsim 6.3c, where the LUTs are implemented as arrays of constants, and additions are implemented by the Wallace tree and ripple carry array. The CSD-based multipliers having the same addition schemes are also synthesized with the same technology library. we have shown the possibility of using LUT based multipliers to implement the constant multiplication for DSP applications.

VI. FUTURE SCOPE

The LUT multipliers for word size L = W = 8, 16, and 32 bits will be coded in VHDL and synthesizing using XilinxISE 12.2i. for the Simulation Part we are going to used Modelsim 6.3c for More Less Area and Less Multiplication Time than CSD.

VII. ACKNOWLEDGEMENT

I would like to articulate my profound gratitude and indebtedness to Assoc. Prof Uma rani, Asst. Prof Naga kishore, Asst. Prof Swetha for guiding and encouraging me in all aspects.

I wish to extend my sincere thanks to Asst. Prof Naga kishore for giving support
