### ABSTRACT

Human activity recognition (HAR) system has a remarkable contribution in developing smart home systems. Thus it is one of the prominent research areas for ubiquitous computing. HAR systems are based on three important aspects. Foremost aspect is to capture human behaviors through sensors. Second and most crucial aspect is extraction of relevant features from data captured via sensors. Last task is classification to recognize which human activity has taken place. Each aspect of HAR poses challenges which are yet to be solved. This paper enlightens state-of-art methods and research work carried in this field by carrying a literature survey. This paper describes each of prominent research models by highlighting their methodology, uniqueness and research gaps. Furthermore this review represents comparative study and result findings of discussed existing techniques.

### I. INTRODUCTION

Human activity recognition (HAR) is the process of automatic identification of human activity captured by the sensor. There is wide range of human activities from static postures (like standing or sitting) to steady transitions (like from sit to stand or stand to sit) and to repetitive activities (like running, jogging). Recognition of these human activities is very much vital to develop smart home devices or IOT devices which can predict events based on them. For instance, HAR can be applied on bank surveillance data to detect burglary and other crime events. HAR is based on three general steps: capturing of human activities by sensors, preprocessing of sensor signals followed by extraction of relevant features and classification so as to identify which human activity has taken place.

Research has been carried out using various data capturing devices like video based sensors, wearable body sensors, wireless sensors and mobile phone sensors [1-16]. Out of them, wearable and mobile phone sensors are prominently used due to its less cost, easiness to use and mobility to carry anywhere. Wearable body sensors can be kept at different body locations (like ankle, wrist, arm, hip, thigh) chosen by researcher [1-3,9]. Trending research has been carried out using signals from smart phones [9, 11-15].

Generally, signals from accelerometer, gyroscope and magnetometer sensors have been processed by HAR researchers because these

sensors are capable of capturing most relevant human information [4, 5]. Signal pre-processing is performed to reduce noise and spikes in signal. It is also desirable to filter out informative components from signals. For example, there are two components (gravity and motion component) in acceleration signals. Gravity component is responsible for distinguishing static postures and motion signals are useful for recognizing transitional and repetitive actions. After signal processing, feature extraction phase comes into picture. For motion signals, Statistical features (mean, power, standard deviation, entropy, correlation etc) are computed because of their high interclass variability [1,2,6,7,8]. Time domain features (like mean, acceleration, power, standard deviation etc) and frequency domain features (like location of peaks, DFT coefficients etc) are mostly extracted by Smartphone HAR researchers.[9, 12]

For classification which is the last stage of HAR, there are plenty of classifiers. Studies have revealed that choice of classifier is based on type of activity recognized, for instance decision trees classifiers are popularly used for classifying activity involving repetitive movements( like walking) [1,2,4,6,15] and type of sensors used, for instance , deep learning techniques are currently used to recognize recorded by Smartphone sensors[11,16]. There are three broad categories for HAR classification which is discussed in next section of this survey.

## II. STATE-OF-THE-ART TECHNIQUES

HAR systems are broadly classified into three categories.

Category 1: HAR based on Classical Machine Learning methods

Category 2: HAR based on neural network methods.

Category 3: HAR based on Deep learning models.

There are numerous machine learning (ML) methods that have been used to design HAR system. Most commonly experimented techniques in this category are SVM, decision-trees, hidden

Markov model and K-nearest neighbour. Studies shows that HAR based on neural network and deep learning models outperform than those based on classical ML methods. Approaches based on Artificial Neural network, Convolutional Neural network and recurrent neural networks falls under category 2. Category 3 is gaining lot of popularity in past few years due to its automatic feature extraction ability. Deep Belief network, Restricted Boltzmann machine and deep Boltzmann machine belongs to this category. Below, we describe survey of prominent proposed HRM system for each category.

In [11], author proposed a model based on category 3 approach.

| Future Scope         | This model face some challenges in classification of sitting activities and 12% of them are wrongly classified as standing activities. Chosen dataset does not contain activities with postural transitions. So the above model can be explored to different datasets with wide range of motion. System performance can be improved by feeding new features to CNN channels and by increasing layers and nodes in it.  |          |              |     |       |     |       |     |       |     |       |     |       |              |              |              |       |           |       |             |       |

In reference [13], author has proposed an innovative HAR system by combining category 2 and category 3 techniques.

| Input data detail    | Sensor device : Smartphone<br>Sensors selected for capturing human events: accelerometer and gyroscopes and magnetometer<br>sampling frequency : 50Hz<br>Signals considered for processing: nine axis motion signals of selected sensors.  |       |       |       |       |       |       |    |    |       |       |       |       |       |       |       |     |       |       |       |       |     |       |       |     |       |       |       |       |     |       |       |       |       |       |       |       |     |       |       |       |       |       |       |     |     |       |       |     |       |       |       |     |     |       |       |       |       |       |       |       |     |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |        |       |       |       |       |       |       |       |
| Signal preprocessing | Raw signals are directly used except simple processing. Simple processing involves sliding window segmentation with 50 seconds of step size to each sensor data. This resulted into 235977 samples each of size 200(data of four seconds)*3(for each of three sensor)*3(for each x, y, z axis).  |       |       |       |       |       |       |    |    |       |       |       |       |       |       |       |     |       |       |       |       |     |       |       |     |       |       |       |       |     |       |       |       |       |       |       |       |     |       |       |       |       |       |       |     |     |       |       |     |       |       |       |     |     |       |       |       |       |       |       |       |     |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |        |       |       |       |       |       |       |       |
| Methodology          | Two CNN models namely CNN-7(seven class network) and CNN-2(Two class network) are used for training and weighted voting of these two CNN models is considered in testing phase to recognize a human activity.<br>Proposed CNN architecture consists of five kinds of layers <ul style="list-style-type: none"> <li>• Input layer of input sample size</li> <li>• 2 Convolutional layers with 64 and 32 kernels respectively for feature extraction from input data.</li> <li>• Max-pooling layer for robustness and size reduction of extracted features.</li> <li>• Fully connected layer</li> <li>• Output layer of Softmax function</li> </ul>  |       |       |       |       |       |       |    |    |       |       |       |       |       |       |       |     |       |       |       |       |     |       |       |     |       |       |       |       |     |       |       |       |       |       |       |       |     |       |       |       |       |       |       |     |     |       |       |     |       |       |       |     |     |       |       |       |       |       |       |       |     |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |        |       |       |       |       |       |       |       |
| Experiment results   | 96.11 % accuracy. This model has efficiently identified two confusing activities like going upstairs and walking. <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th></th> <th>GU</th> <th>DU</th> <th>SD</th> <th>RU</th> <th>WK</th> <th>BY</th> <th>SW</th> </tr> </thead> <tbody> <tr> <td>Test1</td> <td>99.28</td> <td>95.61</td> <td>98.20</td> <td>99.08</td> <td>92.94</td> <td>96.38</td> <td>100</td> </tr> <tr> <td>Test2</td> <td>82.89</td> <td>99.43</td> <td>99.77</td> <td>100</td> <td>90.24</td> <td>99.29</td> <td>100</td> </tr> <tr> <td>Test3</td> <td>96.42</td> <td>98.56</td> <td>97.24</td> <td>100</td> <td>97.58</td> <td>95.12</td> <td>95.43</td> </tr> <tr> <td>Test4</td> <td>86.34</td> <td>98.96</td> <td>99.93</td> <td>100</td> <td>85.23</td> <td>99.86</td> <td>99.67</td> </tr> <tr> <td>Test5</td> <td>95.74</td> <td>98.31</td> <td>100</td> <td>100</td> <td>96.27</td> <td>99.88</td> <td>100</td> </tr> <tr> <td>Test6</td> <td>80.18</td> <td>98.99</td> <td>100</td> <td>100</td> <td>85.42</td> <td>99.40</td> <td>99.69</td> </tr> <tr> <td>Test7</td> <td>93.05</td> <td>96.59</td> <td>96.88</td> <td>100</td> <td>92.13</td> <td>93.01</td> <td>99.36</td> </tr> <tr> <td>Test8</td> <td>92.06</td> <td>98.13</td> <td>99.59</td> <td>99.71</td> <td>94.11</td> <td>99.13</td> <td>99.68</td> </tr> <tr> <td>Test9</td> <td>90.29</td> <td>98.32</td> <td>97.76</td> <td>99.49</td> <td>88.99</td> <td>98.29</td> <td>99.71</td> </tr> <tr> <td>Test10</td> <td>93.24</td> <td>97.01</td> <td>97.11</td> <td>99.41</td> <td>90.98</td> <td>90.54</td> <td>99.68</td> </tr> </tbody> </table> |       | GU    | DU    | SD    | RU    | WK    | BY | SW | Test1 | 99.28 | 95.61 | 98.20 | 99.08 | 92.94 | 96.38 | 100 | Test2 | 82.89 | 99.43 | 99.77 | 100 | 90.24 | 99.29 | 100 | Test3 | 96.42 | 98.56 | 97.24 | 100 | 97.58 | 95.12 | 95.43 | Test4 | 86.34 | 98.96 | 99.93 | 100 | 85.23 | 99.86 | 99.67 | Test5 | 95.74 | 98.31 | 100 | 100 | 96.27 | 99.88 | 100 | Test6 | 80.18 | 98.99 | 100 | 100 | 85.42 | 99.40 | 99.69 | Test7 | 93.05 | 96.59 | 96.88 | 100 | 92.13 | 93.01 | 99.36 | Test8 | 92.06 | 98.13 | 99.59 | 99.71 | 94.11 | 99.13 | 99.68 | Test9 | 90.29 | 98.32 | 97.76 | 99.49 | 88.99 | 98.29 | 99.71 | Test10 | 93.24 | 97.01 | 97.11 | 99.41 | 90.98 | 90.54 | 99.68 |

| Future Scope         | This work can be extended to wide dataset and activities captured by different placements of Smartphone.   |       |       |       |       |       |       |    |    |       |       |       |       |       |       |       |     |       |       |       |       |     |       |       |     |       |       |       |       |     |       |       |       |       |       |       |       |     |       |       |       |       |       |       |     |     |       |       |     |       |       |       |     |     |       |       |       |       |       |       |       |     |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |        |       |       |       |       |       |       |       |

In reference [14], author has proposed a novel HAR system based on shallow Recurrent Neural Network (RNN) combined with Long short term memory (LSTN) deep learning algorithm. Thus, researcher has developed a hybrid approach combining category 2 and category 3 techniques.

| Walking                    | 99%  |              |             |              |           |             |                            |       |       |       |       |            |               |            |     |         |     |         |     |          |     |         |     |          |     |
| Upstairs                   | 81%  |              |             |              |           |             |                            |       |       |       |       |            |               |            |     |         |     |         |     |          |     |         |     |          |     |
| Future Scope               | Upstairs activity achieved only 81% of accuracy rate and most of these activities are wrongly identified as walking activities. In future, this rate can be increased. Dynamic windowing architecture can be used in place of fixed windowing scheme. Instead of single tri-axial accelerometer, multiple sensors can be applied.  |              |             |              |           |             |                            |       |       |       |       |            |               |            |     |         |     |         |     |          |     |         |     |          |     |

In reference [15], author has implemented HAR system grounded on machine learning algorithms. Thus, this research falls under category1.

| Future Scope       | Dynamic windowing architecture can be used in place of fixed windowing scheme. This study can be extended to healthcare monitoring and smart city systems with better prediction rates.   |                        |                         |                        |                         |      |        |        |        |     |        |        |        |    |        |        |        |    |        |        |        |      |        |        |        |          |        |        |        |             |        |        |        |

### III.

#### CONCLUSION

This paper has surveyed existing HAR Systems and explained technical aspects of various phases involved in these systems. It also contains comprehensive study of prominent research papers with proposed HAR systems using various techniques like machine learning, neural networks and deep learning. This study briefly reviewed all necessary information like dataset, input detail, methodology, results and future scope related to each explored paper. From mere results (accuracy factor) of proposed systems, we could not conclude that one HAR research work is superior to other. The reason is that these research results are based on various factors, for instance HAR systems working on dataset with only postural activities may achieve higher accuracy than those including transitional

activities. Therefore, during this research survey, we found that a HAR system outcome depends on many factors like activity chosen, location of sensor, features extracted, number of samples selected for training and testing, classifier used, classification method used etc. So we deduce that no single method can be considered best for recognition of any activity.
