#### Abstract

This paper studies the Hamiltonian coloring and Hamiltonian chromatic number for different graphs .the main results are 1.For any integer $n$ greater than or equal to three, Hamiltonian chromatic number of $C_{n}$ is equal to $n-2$. 2. G is a graph obtained by adding a pendant edge to Hamiltonian graph H , and then Hamiltonian chromatic number of G is equal to $\mathrm{n}-1.3$. For every connected graph G of order n greater than or equal to 2 , Hamiltonian chromatic number of $G$ is not more than one increment of square of ( $n-2$ ). Mathematics Subject Classification 2000: 03Exx, 03E10, 05CXX, 05C15, 05C45. Key words: Chromatic number, Hamiltonian coloring, Hamiltonian chromatic number, pendant edge, spanning connected graph.

## I. Introduction

Generally in a $(d-1)$ radio coloring of a connected graph G of diameter d , the colors assigned to adjacent vertices must differ by at least d-1, the colors assigned to two vertices whose distance is 2 must differ by at least d-2, and so on up to antipodal vertices, whose colors are permitted to be the same. For this reason, (d-1) radio colorings are also referred to as antipodal colorings.

In the case of an antipodal coloring of the path $\mathrm{P}_{\mathrm{n}}$ of order $\mathrm{n} \geq 2$, only the two end-vertices are permitted to be colored the same. If $u$ and $v$ are distinct vertices of $P_{n}$ and $d(u, v)=i$, then $\mid c(u)-c$ (v) $\mid \geq n-1-i$. Since $P_{n}$ is a tree, not only is i the length of a shortest $u-u$ path in $P_{n}$, it is the length of the only $u-v$ path in $P_{n}$. In particular, is the length of a longest $\mathrm{u}-\mathrm{v}$ path?

The detour distance $\mathrm{D}(\mathrm{u}, \mathrm{v})$ between two vertices $u$ and $v$ in a connected graph $G$ is defined as the length of a longest $u-v$ path in G. Hence the length of a longest $u-v$ path in $P_{n}$ is $D(u, v)=d(u$, $v)$. Therefore, in the case of the path $\mathrm{P}_{\mathrm{n}}$, an antipodal coloring of $\mathrm{P}_{\mathrm{n}}$ can also be defined as a vertex coloring c that satisfies.
$\mathbf{D}(\mathbf{u}, \mathbf{v})+|\mathbf{c}(\mathbf{v})| \geq \mathbf{n}-\mathbf{1}$, for every two distinct vertices $u$ and $v$ of $P_{n}$.
§1.1 Definition: Vertex coloring c that satisfy were extended from paths of order $n$ to arbitrary connected graphs of order n by Gary Chartrand, Ladislav Nebesky, and Ping Zhang .A Hamiltonian coloring of a connected graph $G$ of order $n$ is a vertex coloring c such that, $\mathbf{D}(\mathbf{u}, \mathbf{v})+|\mathbf{c}(\mathbf{v})| \geq \mathbf{n}-\mathbf{1}$, for every tow
distinct vertices $u$ and $v$ of $G$. the largest color assigned to a vertex of $G$ by $c$ is called the value of $c$ and is denoted by hc(c). The Hamiltonian chromatic number hc (G) is the smallest value among all Hamiltonian colorings of G.
EX: Figure. 1 (a) shows a graph H of order 5. A vertex coloring c of H is shown in Figure. 1 (b). Since $\mathrm{D}(\mathrm{u}, \mathrm{v})+|\mathrm{c}(\mathrm{u})-\mathrm{c}(\mathrm{v})| \geq 4$ for every two distinct vertices $u$ and $u$ of $H$, it follows that $c$ is a Hamiltonian coloring and so hc(c) $=4$. Hence hc $(H)$ $\geq 4$. Because no two of the vertices $t, w, x$, and $y$ are connected by a Hamiltonian path, these must be assigned distinct colors and so $\mathrm{hc}(\mathrm{H}) \geq 4$. Thus he $(H)=4$.

(b)

1. A graph with Hamiltonian chromatic number 4

If a connected graph $G$ of order $n$ has Hamiltonian chromatic number 1 , then $\mathrm{D}(\mathrm{u}, \mathrm{v})=\mathrm{n}-1$ for every two distinct vertices $u$ and $v$ of $G$ and consequently G is Hamiltonian-connected, that is, every two vertices of $G$ are connected by a

Hamiltonian pat. Indeed, hc $(G)=1$ if and only if G is Hamiltonian - connected. Therefore, the Hamiltonian Chromatic Number of a connected graph $G$ can be considered as a measure of how close G is to being Hamiltonian connected. That is the closer hc ( G ) is to 1 , the closer $G$ is to being Hamiltonian connected. The three graphs $\mathrm{H}_{1}, \mathrm{H} 2$ and $\mathrm{H}_{3}$ shown in below figure 2 are all close (in this sense) to being Hamiltonian-connected since hc ( $\mathrm{H}_{\mathrm{i}}$ ) $=2$ for $i=1,2,3$.
$\int_{0}^{0} 1$

$\mathrm{H}_{1}$
$\mathrm{H}_{2}$
$\mathrm{H}_{3}$

## II. Theorem: For every integer $n \geq 3$, hc

$$
\left(\mathrm{K}_{1, \mathrm{n}-1}\right)=(\mathrm{n}-2)^{2}+1
$$

Proof: Since hc $\left(\mathrm{K}_{1,2}\right)=2\left(\right.$ See $\mathrm{H}_{1}$ in Figure 2) we may assume that $\mathrm{n} \geq 4$.
Let $G=K_{1, n-1}$ where $V(G)=\left\{v_{1}, v_{2} \ldots . . v_{n}\right\}$ and $v_{n}$ is the central vertex. Define the coloring c of G by c $\left(v_{n}\right)=1$ and $C\left(v_{i}\right)=(n-1)+(i-1)(n-3)$ for $1 \leq i \leq n-$ 1.Then c is a Hamiltonian coloring of G and hc $(\mathrm{G}) \leq \mathrm{hc}(\mathrm{c})=\mathrm{c}\left(\mathrm{v}_{\mathrm{n}-1}\right)=(\mathrm{n}-1)+(\mathrm{n}-2)(\mathrm{n}-3)=(\mathrm{n}-2)^{2}$ + 1.It remains to show that hc $(\mathrm{G}) \geq(\mathrm{n}-2)^{2}+1$.
Let c be a Hamiltonian coloring of G such that hc(c) $=$ hc (G). Because G contains no Hamiltonian path, c assigns distinct colors to the vertices of G. We may assume that $\mathrm{C}\left(\mathrm{v}_{1}\right)<\mathrm{c}\left(\mathrm{v}_{2}\right)<\ldots<\mathrm{c}\left(\mathrm{v}_{\mathrm{n}-1}\right)$. We now consider three cases, depending on the color assigned to the central vertex $\mathrm{v}_{\mathrm{n}}$.

## Case 1.

$\mathrm{c}\left(\mathrm{v}_{\mathrm{n}}\right)=1$.
Since
$D\left(\mathrm{v}_{1}, \mathrm{v}_{\mathrm{n}}\right)=1$ and $\mathrm{D}\left(\mathrm{v}_{\mathrm{i}}, \mathrm{v}_{\mathrm{i}+1}\right)=2$ for $1 \leq \mathrm{i} \leq \mathrm{n}-2$.
It follows that
$\mathrm{C}\left(\mathrm{v}_{\mathrm{n}-1}\right) \geq 1+(\mathrm{n}-2)+(\mathrm{n}-2)(\mathrm{n}-3)=(\mathrm{n}-2)^{2}+1$
And so
$\underline{\mathrm{hc}}(\mathrm{G})=\mathrm{hc}(\mathrm{c})=\mathrm{c}\left(\mathrm{V}_{\mathrm{n}-1}\right) \geq(\mathrm{n}-2)^{2}+1$.
Case 2.
$\mathrm{C}\left(\mathrm{v}_{\mathrm{n}}\right)=\mathrm{hc}(\mathrm{c})$
Thus, in this case,
$1=\mathrm{c}\left(\mathrm{v}_{1}\right)<\mathrm{c}\left(\mathrm{v}_{2}\right)<\ldots<\mathrm{c}\left(\mathrm{v}_{\mathrm{n}-1}\right)<\mathrm{c}\left(\mathrm{v}_{\mathrm{n}}\right)$
Hence
$\mathrm{C}\left(\mathrm{v}_{\mathrm{n}}\right) \geq 1+(\mathrm{n}-2)(\mathrm{n}-3)+(\mathrm{n}-2)=(\mathrm{n}-2)^{2}+1$
And so
$\mathrm{hc}(\mathrm{G})=\mathrm{hc}(\mathrm{v})=\mathrm{c}\left(\mathrm{v}_{\mathrm{n}}\right) \geq(\mathrm{n}-2)^{2}+1$.

## Case 3.

$\bar{C}\left(v_{j}\right)<c\left(v_{n}\right)<c\left(v_{j+1}\right)$ for some integer $j$ with $1 \leq j \leq$ $\mathrm{n}-2$.
Thus $\mathrm{c}\left(\mathrm{v}_{1}\right)=1$ and $\mathrm{c}\left(\mathrm{v}_{\mathrm{n}-1}\right)=\mathrm{hc}(\mathrm{c})$.
in this case
$\mathrm{C}\left(\mathrm{V}_{\mathrm{j}}\right) \geq 1+(\mathrm{j}-1)(\mathrm{n}-3)$,
$\mathrm{C}(\mathrm{vn}) \geq \mathrm{c}\left(\mathrm{v}_{\mathrm{j}}\right)+(\mathrm{n}-2)$
$C\left(v_{j+1}\right) \geq c\left(v_{n}\right)+(n-2)$ and
$C\left(v_{n-1}\right) \geq c\left(v_{j+1}\right)+[(n-1)-(j+1)](n-3)$.
Therefore,
$\mathrm{C}\left(\mathrm{v}_{\mathrm{n}-1}\right) \geq 1+(\mathrm{j}-1)(\mathrm{n}-3)+2(\mathrm{n}-2)+(\mathrm{n}-\mathrm{j}-2)(\mathrm{n}-3)$
$=(2 n-3)+(n-3)^{2}=(n-2)^{2}+2>(n-2)^{2}+1$.
And so $\mathrm{hc}(\mathrm{G})=\mathrm{hc}(\mathrm{c})=\mathrm{c}\left(\mathrm{v}_{\mathrm{n}-1}\right)>(\mathrm{n}-2)^{2+} 1$.
Hence in any case,
$\mathrm{hc}(\mathrm{G}) \geq(\mathrm{n}-2)^{2}+1$ and so hc $(\mathrm{G})=(\mathrm{n}-2)^{2}+1$.

## III. Theorem: For every integer $\mathrm{n} \geq 3$, hc $(\mathrm{Cn})=\mathbf{n - 2}$.

## Proof.

Since we noted that hc $\left(C_{n}\right)=n-2$ for $n=3,4,5$. We may assume that $\mathrm{n} \geq 6$. Let $\mathrm{C}_{\mathrm{n}}=\left(\mathrm{v}_{1}, \mathrm{v}_{2} \ldots \mathrm{v}_{\mathrm{n}}, \mathrm{v}_{1}\right)$. Because the vertex coloring $c$ of $C_{n}$ defined by $\mathrm{c}\left(\mathrm{v}_{1}\right)=\mathrm{c}\left(\mathrm{v}_{2}\right)=1, \mathrm{c}\left(\mathrm{v}_{\mathrm{n}-1}\right)=\mathrm{c}\left(\mathrm{v}_{\mathrm{n}}\right)=\mathrm{n}-2$ and $\mathrm{c}\left(\mathrm{v}_{\mathrm{i}}\right)=\mathrm{i}-1$ for $3 \leq \mathrm{i} \leq \mathrm{n}-2$ is a Hamiltonian coloring, it follows that $\mathrm{hc}\left(\mathrm{C}_{\mathrm{n}}\right) \leq \mathrm{n}-2$.Assume, to the contrary, that hc $\left(\mathrm{C}_{\mathrm{n}}\right)<$ $\mathrm{n}-2$ for some integer $\mathrm{n} \geq 6$. Then there exists a Hamiltonian ( $n-3$ ) coloring $c$ of $C_{n}$. We consider two cases, according to whether n is odd or n is even.

## Case 1.

$\mathbf{n}$ is odd: Then $\mathrm{n}=2 \mathrm{k}+1$ for some integer $\mathrm{k} \geq 3$. Hence there exists a Hamiltonian (2k-2) coloring c of $\mathrm{C}_{\mathrm{n}}$. Let,
$A=\{1,2 \ldots k-1\}$ and $B=\{k, k+1 \ldots 2 k-2\}$
For every vertex $u$ of $C_{n}$, there are two vertices $v$ of $C_{n}$ such that $D(u, v)$ is minimum (and $d(u, v)$ is maximum), namely $D(u, v)=d(u, v)+1=k+1$. For $u$ $=v i$, these two vertices $v$ are $v_{i+k}$ and $v_{i+k+1}$ (where the addition in $\mathrm{i}+\mathrm{k}$ and $\mathrm{i}+\mathrm{k}+1$ is performed modulo n). Since c is a Hamiltonian coloring.

D (u, v) $+|\mathrm{c}(\mathrm{u})-\mathrm{c}(\mathrm{v})| \geq \mathrm{n}=\mathrm{l}=2 \mathrm{k}$.BecauseD ( $\mathrm{u}, \mathrm{v})=$ $\mathrm{k}+1$, it follows that
$|c(u)-c(v)| \geq k-1$.
Therefore, if $c(u) \in A$, then the colors of these two vertices v with this property must belong to B . In particular, if $c\left(v_{i}\right) \in A$, then $\left(v_{i+k}\right) \in B$. Suppose that there are a vertices of $\mathrm{C}_{\mathrm{n}}$ whose colors belong to A and $b$ vertices of $C_{n}$ whose colors belong to $B$. Then $b \geq a$ However, if $c\left(v_{i}\right) \in B$, then $c\left(v_{i+k}\right.$ belongs to a implying that $\quad a \geq b$ and so. $a=b$. since $a+b=n$ and n is odd, this is impossible.

Case 2.
$\underline{n}$ is even: Then $n=2 k$ for some integer $k \geq 3$. Hence there exists a Hamiltonian (2k-3) - coloring c of $\mathrm{C}_{\mathrm{n}}$. For every vertex $u$ of $C_{n}$, there is a unique vertex $v$ of $C_{n}$ for which $D(u, v)$ is minimum (and $d(u, v)$ is maximum), namely, $d(u, v)=k$. For $u=v_{i}$, this
vertex v is $\mathrm{v}_{\mathrm{i}+\mathrm{k}}$ (where the addition in $\mathrm{i}+\mathrm{k}$ is performed modulo $n$ ).

Since c is a Hamiltonian coloring, $\mathrm{D}(\mathrm{u}, \mathrm{v})+\mid \mathrm{c}(\mathrm{u})-$ $\mathrm{c}(\mathrm{v}) \mid \geq \mathrm{n}-1=2 \mathrm{k}-1$. Because $\mathrm{D}(\mathrm{u}, \mathrm{v})=\mathrm{k}$, it follows that $|\mathrm{c}(\mathrm{u})-\mathrm{c}(\mathrm{v})| \geq \mathrm{k}-1$. This implies, however, that if
$c(u)=k-1$, then there is no color that can be assigned to $u$ to satisfy this requirement. Hence no vertex of $C_{n}$ can be assigned the color $\mathrm{k}-1$ by c .
Let, $A=\{1,2 \ldots \mathrm{k}-2\}$ and $B=\{k, k+1 \ldots 2 k-3\}$.
Thus $\quad|A|=|B|=k-2$. If $c\left(v_{i}\right) \in A$, then $c$ $\left(v_{i+k}\right) \in B$. Also, if $c\left(v_{i}\right) \in B$, then $c\left(v_{i+k} \in A\right.$. Hence there are $k$ vertices of $C_{n}$ assigned colors from B.Consider two adjacent vertices of $\mathrm{C}_{\mathrm{n}}$, one of which is assigned a color from A and the other is assigned a color from $B$. We may assume that $c\left(v_{1}\right) \in A$ and $c$ $\left(v_{2}\right) \in B$. Then $c\left(v_{k+1}\right) \in B$. Since D $\left(v_{2}, v_{k+1}\right)=k+1$, it follows that $\mid c\left(v_{2}\right)-c\left(v_{k+1}\right) \geq k-2$. Because $c\left(v_{2}\right)$, $c\left(v_{k+1}\right) \in B$, this implies that one of $c\left(v_{2}\right)$ and $c$ $\left(\mathrm{v}_{\mathrm{k}+1}\right)$ is at least $2 \mathrm{k}-2$. This is a contradiction.

## § 3.1Proposition: If $\mathbf{H}$ is a spanning connected sub graph of a graph $G$, then he (G) $\leq$ hc (H) Proof.

Suppose that the order of H is n . Let c be a Hamiltonian coloring of H such that hc(c) hc (H). Then $D_{H}(u, v)+|c(u)-c(v)| \geq n-1$ for every two distinct vertices $u$ and $v$ of $H$. since $D_{G}(u, v) \geq D_{H}$ ( $u, v$ ) for every two distinct vertices $u$ and $v$ of $H$, it follows that $\mathrm{D}_{\mathrm{G}}(\mathrm{u}, \mathrm{v})+|\mathrm{c}(\mathrm{u})-\mathrm{c}(\mathrm{v})| \geq \mathrm{n}-1$ and so c is a Hamiltonian coloring of $G$ as well. Hence hc (G) $\leq \mathrm{hc}(\mathrm{c})=\mathrm{hc}(\mathrm{H})$.
§ 3.2 Proposition: Let $H$ be a Hamiltonian graph of order $n-1 \geq 3$. If $\mathbf{G}$ is a graph obtained by adding a pendant edge to $H$, then he $(G)=n-1$.
Proof. Suppose that $C=\left(v_{1}, v_{2} \ldots v_{n-1}, v_{1}\right)$ is a Hamiltonian cycle of H and $\mathrm{v}_{1} \mathrm{v}_{\mathrm{n}}$ is the pendant edge of G. Let c be a Hamiltonian coloring of G. Since $\mathrm{D}_{\mathrm{G}}$ $(u, v) \leq n-2$ for every two distinct vertices $u$ and $v$ of C , no two vertices of C can be assigned the same color by c. Consequently, hc (c) >n-1 and so hc (G) $\geq \mathrm{n}-1$.
Now define a coloring c` of G by

$$
C^{1}\left(v_{i}\right)= \begin{cases}i & \text { if } 1<i<n-1 \\ n-1 & \text { if } i=n .\end{cases}
$$

We claim that $c^{`}$ is a Hamiltonian coloring of G. First let $\mathrm{v}_{\mathrm{j}}$ and $\mathrm{v}_{\mathrm{k}}$ be two vertices of C where $1 \leq \mathrm{j}<\mathrm{k} \leq \mathrm{n}$ -1 . The $\left|c^{1}+\left(v_{j}\right)-c^{1}\left(v_{k}\right)\right|=k-j$ and
$D\left(\mathrm{v}_{\mathrm{j}}, \mathrm{v}_{\mathrm{k}}\right)=\max \{\mathrm{k}-\mathrm{j},(\mathrm{n}-1)-(\mathrm{k}-\mathrm{j})\}$.
In either case, $D\left(v_{j}, v_{k}\right) \geq n-1+j-k$ and so
$D\left(v_{j}, v_{k}\right)+\left|c^{1}\left(v_{j}\right)-c^{1}\left(v_{k}\right)\right| \geq n-1$.
For $\left.\left.1 \leq \mathrm{j} \leq \mathrm{n}-1, \mid \mathrm{c}^{1}\left(\mathrm{v}_{\mathrm{j}}\right)-\mathrm{c}^{1}\right) \mathrm{v}_{\mathrm{n}}\right) \mid=\mathrm{n}-1-\mathrm{j}$, while
$\mathrm{D}\left(\mathrm{v}_{\mathrm{j}}, \mathrm{v}_{\mathrm{n}}\right) \geq \max \{\mathrm{j}, \mathrm{n}-\mathrm{j}+1\}$

And so, $D\left(v_{j}, v_{n}\right) \geq j$.
Therefore,
$\mathrm{D}\left(\mathrm{v}_{\mathrm{j}}, \mathrm{v}_{\mathrm{n}}\right)+\left|\mathrm{c}^{1}\left(\mathrm{v}_{\mathrm{j}}\right)-\mathrm{c}^{1}\left(\mathrm{v}_{\mathrm{n}}\right)\right| \geq \mathrm{n}-1$.
Hence, as claimed, $\mathrm{c}^{\prime}$ is a Hamiltonian coloring of G and so hc $(\mathrm{G}) \leq \mathrm{hc}\left(\mathrm{c}^{\prime}\right)=\mathrm{c}^{1}\left(\mathrm{v}_{\mathrm{n}}\right)=\mathrm{n}-1$.

## IV. Theorem: for every connected graph $G$ of order $n \geq 2$, hc $(G) \leq(n-2)^{2}+1$.

Proof. First, if G contains a vertex of degree $\mathrm{n}-1$, then $G$ contains the star $K_{1, n-1}$ as a spanning sub graph. Since hc $\left(K_{1, \mathrm{n}-1}\right)=(\mathrm{n}-2)^{2}+1$ it follows by proposition 1 that $\mathrm{hc}(\mathrm{G}) \leq(\mathrm{n}-2)^{2}+1$. Hence we may assume that G contains a spanning tree T that is not a star and so its complement T contains a Hamiltonian path $\mathrm{P}=\left(\mathrm{v}_{1}, \mathrm{v}_{2} \ldots . \mathrm{v}_{\mathrm{n}}\right)$. Thus $\mathrm{v}_{\mathrm{i}} \mathrm{v}_{\mathrm{i}+1} \notin \mathrm{E}(\mathrm{T})$ for $1 \leq \mathrm{i} \leq$ $\mathrm{n}-1$ and so $\mathrm{D}_{\mathrm{T}}\left(\mathrm{v}_{\mathrm{i}}, \mathrm{v}_{\mathrm{i}+\mathrm{I}}\right) \geq 2$. Define a vertex coloring c of T by
$\mathrm{C}\left(\mathrm{v}_{\mathrm{i}}\right)=(\mathrm{n}-2)+(\mathrm{i}-2)(\mathrm{n}-3)$ for $1 \leq \mathrm{i} \leq \mathrm{n}$.
Hence
hc $(\mathrm{c})=\mathrm{c}\left(\mathrm{v}_{\mathrm{n}}\right)=(\mathrm{n}-2)+(\mathrm{n}-2)(\mathrm{n}-3)=(\mathrm{n}-2)^{2}$
Therefore, for integers i and j with $1 \leq \mathrm{i}<\mathrm{j} \leq \mathrm{n}$,

$$
\begin{aligned}
& \left|c\left(v_{i}\right)-c\left(v_{j}\right)\right|=(j-i)(n-3) . \\
& \text { If } j=i+1 \text {, then }
\end{aligned}
$$

$D\left(v_{i}, v_{j}\right)+\left(c\left(v_{i}\right)-c\left(v_{j}\right) \mid \geq 1+2(n-3)=2 n-5 \geq n-1\right.$.
Thus $c$ is a Hamiltonian coloring of T. therefore,
$\mathrm{hc}(\mathrm{G}) \leq \mathrm{hc}(\mathrm{T}) \leq \mathrm{hc}(\mathrm{c})=\mathrm{c}\left(\mathrm{v}_{\mathrm{n}}\right)=(\mathrm{n}-2)^{2}<(\mathrm{n}-2)^{2}+1$, Which completes the proof
